J. M. RICHARDSON, LONDON; AND THE OTHER PROPRIETORS.

M.DCCC.XXX.
DIVINATION is often confounded with omen. The two words, however, have peculiar and distinct meanings. An omen is an indication of what is to come to pass, which happens without the person seeking it, or at least being instrumental in producing it; whereas divination is obtaining the knowledge of futurity by some endeavour of our own. It is evident, however, even after this distinction is made, that it will be difficult to determine under which division many supposed indications of future events, to which superstitious people give credence, ought to be placed. The superstitious inferences that are drawn from certain animals crossing the path, and from the flight of birds, &c. are certainly, by this definition, to be considered as omens; but it is not easy to determine whether the superstitious inferences, which were drawn by the ancients from the appearance of the entrails, &c. of their sacrifices, should be classed under the head of divination or omens.

It is not our intention in the present article, to enumerate all the species of divination which have been and are practised by superstitious people; but only to notice those kinds or instances, which are less familiar to general readers, or which are particularly curious.

The Jews had many kinds of divination, most of which are described or mentioned in the Old Testament, or by the Rabbinical commentators on it. Some of these, however, seem to belong rather to the class of omens, than to that of divination. The first kind was performed, by consulting the stars, clouds, signs, tokens, and the like; and is designated in the Old Testament by the word monachēsk. This, though reckoned a species of divination by the Talmud, is evidently a species of omen. The second kind was by a divining cup, which is particularly mentioned in the 44th chapter of Genesis, verses 5 and 15. The third mode was by consulting familiar spirits; and it is singular, that the Hebrew word for this species, is very similar to the word which the Negroes apply to their Oboe man in the West Indies. The 4th species of Jewish divination was by interfering the dead. The 5th seems to have consisted in a species of legerdemain. The 6th is expressed by a word, which signifies a matterer. Besides these, divination was practised by teraphins, by the flight of arrows, by the liver of beasts, by sticks and staves, &c.

The practice of divining by the raphins, or images, by the entrails of beasts, and by arrows, the Jews borrowed from the Egyptians. The last mode, that of divining by arrows, was also very common among the Arabsians, who continued to practise it till Mohammedism prevailed, which, in several parts of the Koran, absolutely forbids it. The arrows used for this purpose were without heads or feathers, and were kept in the temple of some idol, in whose presence they were consulted.

The divination, in general, was made by three only: on one of which was written, "My Lord hath commanded me;" on another, "My Lord hath forbidden me;" and the third was blank. If the first was drawn, it was considered as approbation of the enterprise they were about to undertake; if the second, as disapprobation; and if the third, they drew them over again, till either the first or second was drawn. This practice was also used by the ancient Greeks. The other modes of divining used by the Greeks and Romans, we shall pass over, as familiar to most of our readers. The ancient Germans, besides the mode common to most nations, that of divining by the entrails of beasts, had some so peculiar as to deserve notice, especially as they seem to confirm the hypothesis of the Persian origin, or affinity of the Goths; for, like the Persians, their most favoured species of divination was drawn from the horse. Tacitus informs us, that by the neighing of a white horse, which had never been subject to the yoke, they foretold the success of the enterprises they were about to undertake. Another mode of divining by this animal was used by the Vandals. When they were about to commence hostilities, they fixed three rows of spears upright in the ground, and across each row they placed another spear; a horse was then brought out by the priest, and led up to these rows, and if he touched either of them first with his right foot, the omen was propitious, but if with his left it was adverse.

The kinds of divination, to which superstition in modern times has given belief, are not less numerous, or less ridiculous, than those which were practised in the days of profound ignorance. The divining rod, which is mentioned in scripture, is still in some repute.
DIVINATION.

in the north of England, though its application is now confined principally to the discovery of veins of lead ore, seams of coal, or springs. In order that it may possess the full virtue for this purpose, it should be made of hazel. Divination by Virgilian, Horacian, or Bible lots, was formerly very common; and the last kind is still practised. The works are opened by chance, and the words noticed which are covered by the thumb; if they can be interpreted in any respect relating to the person, they are reckoned prophetic. Charles I. used this kind of divination to ascertain his fate. The ancient Christians were so much addicted to the sorte saecularum, or divining by the Bible, that it was expressely forbidden by a council. Divination by the speal, or blade bone of a sheep, is used in Scotland. In the Highlands it is called sleina-reached, or reading the speal bone. It was very common in England in the time of Drayton, particularly among the colony of Flemings settled in Pembrokehire. Camden relates of the Irish, that they looked through the bare blade bone of a sheep, and if they saw any spot in it darker than ordinary, they believed that somebody would be buried out of the house. The Persians used this mode of divination. Another kind was by a plant called bachelors buttons. They were carried in the pockets by the men, and under their apron by the women, and if they continued fresh, good luck in courtship was portended; but if they soon faded, the reverse. Palmistry was one species of divination, which seems to have been studied in a very regular manner. The lines of the hand were distinguished into formal lines; table lines; the line of fortune; the line of life or the heart; the line of the liver, &c. Names were also given to the fingers. The little finger was called the ear finger, because it was used by our ancestors to clean their ears. Divination by the finger nails was another species; though this, as well as some of the others we have noticed, do not properly come under the head of divination. From the spots on the nails, it was supposed not only that the temper might be known, but future events foretold. The divination by sieve and shears, is mentioned by Butler as common in his time. (Hudibras, part ii. can. to 3, line 569.) This kind is also mentioned by Theocritus. It was used to discover thieves. The points of the shears were stuck in the wood of the sieve, which was balanced on the fingers of two persons. Some words out of the 50th Psalm were then read, and the name of the suspected thief pronounced. If the sieve turned suddenly round, he was the guilty person. A Bible and key was used for the same purpose, and in the same manner. Divination by onions and faggots is a German custom, though it seems also to have prevailed in England in the middle of the 17th century. Onions, with the names the fancy applied to them, were put by girls near the chimney, and the first that sprouted bore the name of the destined husband. If after this they wished to know his disposition, they went to the wood-stack and drew a faggot; if it were strait, and without knots, his disposition would be gentle. Divination by a green ivy leaf, which was laid in water on New Year's Eve. It was not to be examined till twelfth night. If it were spotted, the person for whom it was laid will be sick next year. If the spots were near the top, the sickness will be in the head; if in the middle, in the heart; if all over, it portends death. Divination by flowers, was practised in Sicily in the time of Theocritus; and Kerwick mentions divination by the daffodil, as common in England in his time. If it hung its head towards a person, his health would decline. The divinations respecting pulling the bride-cake through the wedding ring, and those practised at Hallow e'en, as described by Burns, are well known.

In Wales, men and girls seek an even leafed sprig of ash. The first who succeeds calls out cynivor, which is answered by the first of the other sex that succeeds; and these are to be married. In what is termed a scalding of peas, a bean is put into one of the pease; whoever gets this is to be married first. Apple perings fung over the head; form the first letter of the name of a person's sweetheart. But one of the most singular species of divination used for this purpose was the following: Girls stuck an apple kernel on each cheek, and to each kernel they gave the name of one of their sweethearts; that which fell first, indicated that the person whose name it bore, was not sincere in his love. On the subject of love and courtship, indeed, various kinds of divination were practised besides those already described, with one or two of which we shall conclude this article. Snails were set to crawl on the hearth, and they were supposed to mark in the ashes the initials of the person beloved. This was principally used on May day. On Valentine's day, there were different kinds of divination. The night before, five bay leaves were to be put under the pillow, and if the sweetheart were dreamt of, the marriage was to take place that year; or an egg was to be boiled hard, the yolk taken out; put into salt, and eat along with the shell, at bed time, without speaking or drinking after it, the dream would in this case point out the sweetheart. By others, the names of their lovers were written on bits of paper, which were rolled up in clay, and put into water; the first that rose was to be the valentine. Brand's Popular Antiquities, vol. ii. 4to, will supply the curious on this subject with many other particulars. (w.s.)

DIVING,

The act of descending to a considerable depth beneath the surface of water, and continuing in that situation a sufficient time, to collect valuable articles from the bottom of rivers, or the sea; such as pearls, sponges, coral, and other submarine productions; or to recover goods lost by shipwreck.

Man does not appear to have been intended by nature for diving, or at least for continuing any time under water; regular respiration being so necessary to his life, that, by the greatest inspiration, he cannot carry down a larger quantity of air than will supply him for two minutes. This we learn from Dr Halley is possible, as he observed in a Florida Indian diver at Bermudas; but it is certainly an extreme case, for ordinary persons generally begin to feel a danger of suffocation in the space of half a minute after submersion in water. The Doctor relates, that those who dive in the Archipelago for sponges, have a practice of taking in their mouths a piece of sponge dipped in oil, with a view, he supposes, of inhaling the air which the sponge contains; and from this they are enabled to dive a longer time than others who employ no artifice. It is not easy to conceive how this can assist the diver's breathing; for the introduction of any foreign substance into the mouth
must necessarily diminish the quantity of air he can take down: But we have been lately informed, that the real object of taking oil in their mouth is to calm those small waves on the surface of the sea, which prevent the light being so steadily transmitted to the bottom, as is necessary to enable the divers to find the small objects they search for without delay. By ejecting a little oil from their mouths, it rises to the surface, and spreading upon it, calms the waves in a most remarkable manner, and gives a brilliant light at the bottom. This singular property of oil has been long known, and is practised in many other ways to allay the agitation of the sea, by fishermen and mariners. A diver has to go through a very great exertion in holding his breath when deep under water; for it should be observed, that an equally great difficulty with the want of air arises in diving at considerable depths, from the pressure of the water upon the surface of the body, tending to compress every cavity within it. It requires a very great muscular strength in the diver to resist this action; no breast-plate or other contrivance can defend him, unless it is made to exclude perfectly the water from his breast, and of sufficient strength to bear the pressure; in which case it would become too heavy and cumbersome to permit his speedy descent and return. To dive at all requires long practice, and habitual exposure to the weight of the water, after the habit of retaining the breath is sufficiently acquired; and it is observed, that when the most expert divers continue to dive repeatedly for any length of time in deep water, their eyes become bloodshot, and a spitting of blood, induced from the great exertion. People who are accustomed to the water from their infancy, will at length be enabled not only to remain much longer under water than could be supposed, but acquire a kind of amphibious nature, so that they seem to have the use of all their faculties, as well when their bodies are immersed in water, as when they are on dry land. Many savage nations are remarkable for this, and, according to the accounts of our late voyagers, the inhabitants of the South Seas islands are such expert divers, that when a nail or any piece of iron was thrown overboard, they would instantly jump into the sea after it, and never fail to recover it, notwithstanding the quick descent of the metal. Even among civilized nations, many persons have been found capable of continuing an incredible length of time under water.

The most remarkable instance of this kind is the famous Sicilian diver Nicola Pesci, who, according to the marvellous account given by Kircher, had from his infancy been so used to the sea, that at last it became his most natural element. It is said he was frequently known to spend five days in the midst of the waves, without any other provisions than the fish which he caught there, and eat raw. He often swam over from Sicily into Calabria, which is a tempestuous and dangerous passage, carrying letters from the king, and as frequently swam among the gulls of the Lipari Islands, without any apprehension of danger. "In aid," says Kircher, "of these powers of enduring the deep, nature seemed to have assisted him, in a very extraordinary manner; for the spaces between his fingers and toes were webbed as in a goose, and his chest became so very capacious, that he could take in at one inspiration, as much breath as would serve him a whole day." A length, however, we are told, this extraordinary person met his fate, in exploring the depths of the whirlpool of Charybdis, at the instance of the king, who, after he had once succeeded in fetching up a golden cup that had been thrown in, ordered him to repeat the experiment. The authenticity of this account depends wholly upon the authority of Father Kircher, who assures us he had it from the archives of Sicily, and that the Sicilian king above mentioned was King Frederic. But, notwithstanding this assertion, the whole is so marvelous, as to prevent us from giving any particulars of the wonders which his hero saw at the bottom of the celebrated Charybdis.

From the many important purposes to which the art of diving is applicable, and from that very general spirit of enterprise which induces ingenious men to attempt what is exceedingly difficult, or apparently impossible, the mechanical projectors of the last two centuries have been stimulated to produce a multitude of inventions for enabling divers to descend to great depths, and to continue under water at pleasure. Of all these, what is called the diving bell has been found the most useful, no other contrivance having been brought to such a degree of perfection in all its parts, as to come in competition with it, for descending in deep water; though some have been found very useful, in particular situations, where the water is of so great depth. We have given descriptions of the different diving bells in a separate article, and shall here briefly notice other inventions for diving, which have come to our knowledge.

The early contrivances are most of them suits of armour, made water-tight by leather, and provided with large head pieces or helmets, to which flexible tubes are attached, for conveying down fresh air, and returning that which has become unfit for respiration; the fresh air being forced down one pipe by bellows, or other means, and allowed to return by another. These pipes supplied the diver with air, whilst the armour, by keeping off the pressure of water from his breast, allowed his chest to dilate upon inspiration. A number of different contrivances of this class are to be found detailed in Leopold's Theatrum Machinarum Hydraulicae, though none of them have been found of extensive use, except in small depths, such as twelve or fifteen feet. At much greater depths this method is not practicable, because it is necessary that the diver should have his limbs exposed, or only covered with a flexible covering, in order to enable him to do any good at the bottom of the sea; and the pressure on the limbs is then so great, as to obstruct the circulation of blood, in the same manner as ligatures would do, whilst those parts of the body which are within the armour being relieved from pressure, the blood is forced from the limbs into them, and causes intolerable pain and distress. It is also difficult to construct an armour sufficiently strong without being unwieldy, and the least defect will fill the whole with water, and endanger the life of the diver, who may be drowned before he can be drawn up.

In Plate CXXXI. Fig. 1, we have given a representation of one of the best of these contrivances, which may be of very extensive use in small depths. It was proposed by H. Klingsert, and is described in a pamphlet published at Breslau in 1796. The harness or armour is made of strong tinfoile, in the form of a cylinder, which encloses the diver's body and head: it consists of two parts, that he may conveniently put it on; also a jacket, with short sleeves, and a pair of drawers of strong leather, all nominal. The armour. The armour. AA is the upper part of the cylinder, having a glo-
bular top to contain his head. It is fifteen inches in height, and its diameter is adapted to the size of the diver at the hip bone. BB is the lower half of the same diameter, and of such length as to meet the other at the dotted line D. Both are provided with strong iron hoops, on the inside of the tin plate at a b and c; also two other pieces of hoop, which cross each other on the inside over his head, and support the globe top. The leather jacket D, dd, and drawers Ex, ee, are attached to the cylinders by buttons, as the Figures show; and to make the joints water-tight, three hoops of brass, a, b, and c, are fitted over each joint, to bind the leather forcibly upon the parts where the cylinders are strengthened by the internal hoops before mentioned. To prevent the leather slipping off, if the buttons should fail, a rim of brass wire is soldered round the circumference of the cylinders, outside, at each joint, and the hoops are put on beyond these. The hoops are made of brass plate; and their ends are turned up and fitted with screws, by which they can be drawn very tight upon the leather. The cylinder AA, BB, has holes cut in it, for the arms to go through; and the upper and lower halves separating at D through these holes, overlap each other a small quantity, by the lower one entering the upper one. The jacket when fastened on, keeps the two halves together, and makes a tight fitting with the arms, the sleeves being bound round them at d by small screw hoops of the same kind as the large ones. The drawers have also brass garters c, e, to fit the leather close round at the knees. f, f, are two holes in the upper half, into which the eye glasses are screwed; and g is a third aperture, provided with a screw to connect the two breathing pipes h and i with the machine, in such a situation that the mouth-piece of the pipe h may be opposite the diver's lips; k is an opening for the diver to breathe through; when out of water it is closed by the screw cap j, before he descends. The breathing pipes are three-fourths of an inch diameter in the inside, and of a sufficient length to reach the surface of the water: they consist of a strong brass wire, wound into a spiral form, and covered with stout leather. To save expense, six yards of the pipe from the mouth may be made in this manner, and the remainder of tin plate tubes, in lengths, united by short leather pipes, to form flexible joints. The pipe h is to supply fresh air, and it is this which joins to the mouth piece within the machine; the other pipe opens into the cavity of the machine. The diver therefore draws his breath through the mouth piece, from the pipe h; but, on expiring, throws the air through his nostrils into the cavity of the machine, from which it escapes by the pipe i to the open air. By this means the air within the machine always remains at the same state of elasticity, and every time he inhales air from the mouth piece, the dilation of his breast forces an equal volume of air from the cavity of the machine, through the pipe i. It is only by this arrangement of the pipes that a man can breathe at all when enclosed in so small a space; for though the harness will defend his breast from the pressure of the surrounding water, it will not be possible for him to breathe and return the air through a single pipe, as some inventors have proposed, through his body must always distend a space equal to the volume of air he inhales; and as the machine does not contain much more than a cubic foot of air, it would make too great a resistance to compression for him to obtain a sufficient supply to support life. A simple experiment will evince the truth of this: Let any one take a cask of one or two cubic feet, and placing his mouth to the aperture, endeavour to return into it the air he has inhaled, it will be found to require an exertion too great to be continued. By allowing a larger space round the diver, the difficulty would be diminished, but would render the apparatus inconvenient. Another insuperable objection to breathing through a single pipe is, that the content of the pipe, unless extremely short and of small bore, will bear a great proportion to the quantity of air the diver inhales at each inspiration; consequently he will, at each time, be obliged to take back as much of the air he had before breathed, as will fill the whole pipe, and only obtain as much fresh air as the difference between the quantity he inhales and the content of the pipe. Nor is it practicable, as others have proposed, for him to breathe through one pipe, and then throw the air out into the water through a mouth piece, which, of course must have a valve, to prevent the water entering the machine. In this case it would require him to condense forcibly the air contained in his lungs, until its expansive force equalled the pressure of the surrounding water, and opened the valve, which is clearly impracticable at a very small depth; for admitting that, by the muscular exertion of the checks, he was able to condense the air sufficiently, still he could not expel the whole of the air from the cavity of his mouth; and this quantity when reduced to its expanded state, would mix with the fresh air, and form a considerable portion as to contaminate it. The construction of the mouth piece of Klingert's mouth machine, which is screwed in at the aperture g, is fully explained by the section, Fig. 2. Here h and i are the ends of the flexible tubes, screwed into a box v, v, which has a male screw t, to fit into the aperture g, Fig. 1. The box has a partition which keeps the two passages separate, the upper one communicating from the pipe h to the ivory mouth piece x, and the other opening at z into the machine, connects it with the pipe i. The leather drawers have a framing of iron within them to resist the pressure. This frame, which is shown separate in Fig. 3, consists of a semicircular piece of iron hoop, v m, also shewn by the dotted lines m m, Fig. 1, extending between the diver's legs, and fastened to the lower extremity c c of the cylinder, at the front and back; also two irons n n, outside the thighs, which are jointed to the cylinder at the points c, c, Fig. 1, and extend down to c, where they are firmly attached to a hoop surrounding the thigh. There is another hoop for each thigh higher up, at the point r. These hoops are farther connected by irons at p p, which, at the upper ends, are fitted to slide upon the semicircular hoop, as shewn at s, Fig. 3. By this means, though the frame is abundantly strong, the diver is at liberty to walk; the joints at c, c, and the traversing of the irons p, upon the hoop m, admitting the motion of his thighs, because the centres of motion correspond with the hip joints. The leather drawers are fitted over the framing, and sewed to the hoops; but if the depth is to be considerable, the inventor advises a net of small chains to be stretched over the frame, in different directions, before the leather is put on. As it is not possible to sew the leather so completely as to prevent wholly the water from leaking in at the seams, in all probability a pump is fixed at l, in front of the machine, to extract the water when it has accumulated, so as to rise a few inches in the cylinder. To prevent leakage as much as possible, the jacket and drawers must be very carefully made with slips of leather sewed very closely over the seams. The pipes must be made of the very best leather, which will be rendered very close in its pores, and prevented from becoming hard, by dressing it with a composition of the leather.
Diving.

PLATE CCXXXI.

Fig. 1.

Klingert's machine, to enter into a detailed description of any other of the same class, such as Kessler's water armour, which he proposed in 1617, and many others, as the one which we have described seems to contain all that is good in the others. Some of them have an essential difference in the apparatus for breathing, viz. by forcing down the air by bellows or a pump, and thus condensing it into the machine, until its elastic pressure is sufficient to repel the pressure of the water. The soul air which has been breathed, may, in this case, be suffered to escape from the machine through a valve into the water, or it may be conducted to the surface by a pipe. Of this kind is the apparatus contrived by Mr Tonkin, and employed for some time in raising parts of the wreck of the Abergavenny East India ship, which was unfortunately lost off Weymouth in 1804. It consisted of a body of copper with iron boots, put together and jointed in the manner of coats of mail; the whole is then covered with leather, and afterwards with canvas, painted white to distinguish it under water. The arms are made of strong water proof leather; and the place for sight is about 8 inches diameter, glazed over with a plate of glass an inch thick. The diver is sunk in this machine by means of weights, fastened equatorially round the waist of it; and he is suspended by a rope, by means of which his situation is changed at pleasure. A flexible air tube communicates with an air vessel in the boat above. Through this tube the diver gives his instructions, and obtains his supply of fresh air. This machine was used with very good effect in a depth of near 7 fathoms water, and enabled the diver to direct the operation of several curious machines, such as saws for clearing away the ship's decks, and making sufficient openings to give him access to the treasure below, as well as tongs, &c. for taking up the heavy goods by tackle in the vessel above.

The next class of diving machines which we shall describe, are those in which the diver is shut up, with a sufficient quantity of air to supply him a considerable time; and in this he descends, proper contrivances being provided, to enable him to work at the bottom, where he can only continue as long as his supply of air is sufficiently pure for respiration, which will be but a short time, unless the machine is enormously large; for a man will, according to an experiment of Dr Halley's, consume a gallon of air in the course of a minute, and as he throws out the impure air to mix with the rest, it will so contaminate it, that by the time he has breathed one half the air, the whole will become very unfit for respiration, and oblige him to be drawn up to recruit it. We understand, that in a vessel containing a ton, a single man may remain an hour without injury.

The diving bladder contrived by Borelli, is the earliest of this kind. It is described in his Opera Posthuma, to consist of a vessel of copper, which he calls the vesica, or bladder, and is about two feet diameter. This is to contain the diver's head, and is to be fixed to a great skin habit, exactly fitting to the shape of his body. The person carries an air pump by his side, by means of which he may condense or rarify the air in the vesel, and thus make himself heavier or lighter on the same principle as fishes do, by contracting and dilating their air bladder. Within this vesica there are pipes, by means of which a circulation of air is contrived; and, by this arrangement, Borelli supposed the objections to which all other diving machines were liable would be obviated, particularly that of their air; "the moisture by which it is clogged in respiration, and by which

of the machine, the air is drawn out of the water, the pipes unscrewed, and by blowing fresh air with a pair of bellows at one aperture, the foul air is driven out at the other, and the machine prepared for another descent.

The diver has the power of ascending or descending with the machine at pleasure, without being dependent upon those in the boat, by means similar to the air bladder of fishes. Thus the ballast is so adapted to the size of the machine, as to make it sink so far that only a cubic foot of it remains above water. In this state, an additional weight of 100 pounds will depress it below the surface, or make it sink to the bottom. The effect of adding extra weights is produced, by diminishing the volume of contained air, by condensing it into a smaller space. To accomplish this, a large cylinder is applied in the bottom of the vessel, and provided with a piston, which, by a rack and pinion, can be moved from one end of the cylinder to the other, when the diver turns a handle, coming through the side of the machine, and communicating motion by a worm and wheel to the pinion of the rack before mentioned. The lower end of the cylinder is open to the water, and the upper end opens within the machine; therefore, when the diver turns the handle in the direction to raise up the piston in its cylinder, it necessarily diminishes the bulk of the included air, and the machine will sink; but on depressing the piston in the cylinder, it will ascend again. The inventor proposed to furnish the machine with two small oars to move it in the water, and an anchor or grapnel to make it fast, whilst the diver walks about on the bottom, within the limits of the length of the pipe, to examine sunk bodies, and discover the best mode of raising them. To prevent danger from any accident happening to the machine, the diver is to be provided with the means of quickly detaching the pipes from the machine, and retaining a sufficiency of air in the armour to carry him to the surface, when he throws off the weights suspended from his girdle.

Mr Klingert also mentions a lantern of his invention which may be very useful to a diver at the bottom of the sea. The principles of its construction he keeps secret, but asserts that it is very simple, and that a candle inclosed in one of them will burn in every kind of air in mines and pits, where all other lights are extinguished. It contains a space equal to a cubic foot, and the candle will burn without any addition of fresh air from without for 2 or 3 hours.

Plate CCXXXI. Fig. 4, represents a diving machine invented in 1753 by Mr Rowe. It is a trunk or hollow copper vessel aa BD, soldered or rivetted together with strength proportioned to the depth of water where it is to be fixed. It contains the diver’s body, and also a sufficiency of air for the time he intends to dive. He enters with his feet first at the open end aa, which is then closed by a lid or cover screwed on, by a number of screw bolts passing through the flanges a, a. The vessel is bent at D, for the bearing of the diver’s knees, and has sufficiency of leaden ballast at G, to sink it in the right position. bb are two hoops surrounding it, which, at the same time that they strengthen it, afford points of suspension by a bar d, which is attached to them, and is pierced with several holes to admit a span upon
the rope E, which is so adjusted, as to suspend the whole, with the diver in it, nearly in the position of the Figure, when he will be in a convenient posture for working with his arms, which come through openings k in the vessel, to which sleeves e, of very strong leather, are attached by a hoop or ring, screwed to the vessel with the leather between them. The sleeves are lined with cloth, and the edges round the holes k are defended by soft quilting, from hurting the diver's arms by the pressure, as well as to prevent the sleeves and his arms being thrust inwards. i is an aperture covered by a strong lens, for the diver to see through. At m and n are two other openings in the upper part of the vessel, covered by screw caps, which are removed when fresh air is to be introduced into the machine by the nose pipe of a pair of bellows, being applied to force fresh air into one, and drive out the foul air at the other. The lower opening at n is also of use, to pump out any water which may leak through at the joints, though this is as much as possible prevented, by fitting leather, at m in the joints of the cover, and the caps m, n before they are screwed tight. The mass of lead G is fastened to the lower side of the vessel in a line between the diver's arms, by means of the hoops b, B. On this the whole rests if it comes to the ground, and remains in a proper position for the diver to work, and fasten ropes to any thing which is to be drawn up, as shewn in Fig. 5.

If the water is very deep, the diver must wear a kind of saddle on his back, which having a ridge touching the top part of the vessel withinside, enables him to keep his arms properly out of the apertures, otherwise he would not have strength to resist the pressure acting upon the surface of the arms and sleeves, which forces them into it with a weight proportional to the quantity of surface exposed, end to the depth of water. The diver gives his instruction to those above by a small line r, which is laid through a staple at the side of the machine, and has a handle always hanging in reach of the diver's hand. The upper part of this line is held by a person in the boat or ship above, to whom any signal is given, by the diver snatching or twitching the line a certain number of times, as has before been agreed upon. This is immediately felt by the person above, who give orders accordingly. The size of the vessel is such, that he can continue at the bottom about half an hour, without any pipes or other supply, and will be enabled to do many things very readily; such as recovering moorings, chains lost in rivers or harbours, hooking ropes for weighing up lost anchors, or any other purpose where there is free access to the objects sought, though in entering and searching the wrecks of ships, it would be less convenient than some others which we shall describe. To dive in still water with this machine, requires no other rope than that marked E, which suspends its weight from the yard arm of a ship, and the signal line r to communicate orders to those above. If it is required to dive in a rapid current, a difficulty will arise from the water carrying the vessel out of its direction. In this case, the method shewn in Fig. 5. will be very effectual. It represents a vessel lying at anchor by the cable or hawser a, so as to be up-stream of the spot to which the diver is to descend; then by veering away, or taking up the hawser, she can be brought over the place at pleasure. At the end of the vessel's gaff, a middle block l. is lashed, and a small hawser f f f y rope through it. One end of this has a stream anchor, or a grapnel N, bent to it, with a considerable weight attached to the stock. The other end of the hawser is conducted to the windlass at R, through a leading snatch block fixed on the deck at k. By this means it may be taken in, or given out, as the tide rises or falls; and, by the position of the gaff, the hawser stands clear over the vessel's side, to guide the diving vessel B, when it is let down or taken up, in the following manner: A traveller, or iron ring t, is put upon the hawser f, to run freely up and down upon it, by means of two ropes s and n. The rope s passes through a small block q at the gaff, and goes down to the deck, the lower end being fastened to the traveller. The other rope n passes through a block p, lashed to the shank of the grapnel. The ends of this are conducted through another sheave of the block q, and also brought on the vessel's deck where both are, and belayed on the gunnel. Now by hauling the rope s, and letting go the other n, the traveller is drawn up on the hawser, and vice versa. The traveller i carries a block x for the rope v, which is attached to the engine B at one end, and goes up to the block M at the end of the gaff. It is then taken down on deck through the block q, and held by a sufficient number of hands to guide the engine. E is another rope suspending the weight of the engine from the vessel's quarter, and is held by several men, r being the signal line, as before mentioned.

A vessel moored in this manner by the head in a rapid stream, will steer by the rudder to turn her side-wise within small limits; but in this motion she turns upon a centre of motion very nearly coincident with the hawser f, so as not to disturb the grapnel N. The diver being put into the vessel, and the joints screwed up tight, the rope v is hauled till the engine comes home to the block x on the traveller, as it lies upon the deck; then by hauling the end of the rope v, the engine is hoisted clear; and by slackening it out, and at the same time hauling n, the traveller and engine are taken down perpendicularly to the bottom. The rope E being slacked away by a round turn over a timber head on the vessel's quarter, to lower it gradually when the diver gives the signal of being near the bottom, the rope E is held fast, and r being still given away, the engine is conveyed in the easiest manner to the situation shewn by the Figure, where the object sought is supposed to be. In this condition, he can be moved with great precision to any situation lie directs by the signals. Thus by hauling or giving out the rope v, he will move up stream or down stream; and by the steerage of the vessel's rudder, will be moved athwart the stream to the required situation; but if this is not exactly known before the diver descends, it will be prudent for the vessel to moor with two anchors at a distance asunder, the cables of both meeting on her bow a, with an angle in this situation. By giving out one cable, and taking up the other, she may be made to ride at any part of the stream. A diving machine of this kind may, on many occasions, be useful, and to descend in it occasions no danger to the diver, provided he is suspended by tackle, which will bring him up quick enough when he gives the signal. When he wants fresh air, the vessel, if made of copper, must be either turned or japanned on the inside, otherwise it would give a most nauseous taste to the diver confined within it, which is not less pernicious than offensive.

Fig. 7. represents a very useful tackle or tongs, for taking up articles from the bottom. Every diver should have this provided with several pairs of these of different dimensions. In small depths they will bring up goods Fig. 7. without any person descending; but when they are
Diving.

The dancing, by a diver at the bottom to take up the goods which are wanted, they are extremely expeditious in their operation. A, represents the rope let down into the water. It is attached to the pole or iron shank B, which at the lower end has two arms abc, abc joined by a common piece d, which slides upon B, and has a shackle with the rope D fastened to it. When these tongs are let down by the rope A, the weight of the socket, and links ad, disposes the claws to open as in the figure, and in this state they are lowered or guided by the diver upon the goods to be recovered. The rope D is then drawn up, which raising the shackle, closes the claws upon the object between them, and grips them so hard that they will seldom slip, because the greater the weight the more powerfully they close together. If they fail of catching it the first time, they may be opened again by drawing the rope A, to make another trial.

The experiment of Drebé's submarine boat, is not the only attempt which has been made to navigate a vessel under water, without any communication with those at the surface, but having the means of ascent or descent, and making progress in any direction, independent of assistance from without. The celebrated Bishop Wilkins, in his Mathematical Magic, dated 1648, has given a chapter on the subject, in which, after referring to the successful experiments of Drebé, he enumerates the benefits of these submarine enterprises, and with a visionary facility, which is truly extraordinary, removes all difficulties. Thus for letting out and taking in such things as the nature of the voyages may require, he recommends bags or flexible tubes, somewhat resembling the scupper bags of ships. The progressive motion may, he observes, be produced by fins or oars, which will operate with ease when the vessel is truly equipped; and if swiftness could not thus be obtained, still he supposed the observations and discoveries to be made at the bottom of the sea would abundantly recompense for that defect. The greatest difficulty, in his apprehension, would be in the necessity of renovating the air for respiration and combustion; but for removing this, he advances the probability, that custom may render men capable of living in air of inferior purity; and besides, he has several philosophical views and projects. The convenience and advantages of submarine navigation which he enumerates are, 1st, Privacy, as a man may thus go to any part of the world invisible, without being discovered or prevented. 2d, Safety, from the uncertainly of tides and tempests which vex the surface, from pirates and robbers, and from the ices, which so much endanger other voyages towards the poles. 3d, It may be of use to undermine and blow up a navy of enemies, or to relieve a blockaded place. As the prospect enlarges in the mind of our author, he proceeds to contemplate the inestimable benefits of submarine discoveries; experiments on the ascent and descent of submerged bodies; the exploration of the deep caverns and passages of the waters of the ocean; observations on the nature and kinds of fishes, with the allurements, artificial, and treacherous, which may be successfully practised upon them during so familiar a residence in their territories; the food and oil they may afford; the probability of fresh springs for a supply of water at the bottom of the sea; the facility of recovering submarine treasures, whether lost, or naturally produced beneath the ocean.

The nearest approaches to realizing the bishop's ingenious conoeits, besides the experiment of Debroel, was made by Mr. D. Bushnell of Connecticut, in America, who, in 1787, published a description of a submarine vessel of his invention, in which it was found very practicable to travel under water; though we cannot regret, that he failed in his ultimate view of destroying ships, by approaching them under water, and fixing a magazine to them, which was to explode at the expiration of a certain time, after the diver left it detached from his vessel. The whole invention displays very great ingenuity and originality of idea. It is minutely explained in the publication alluded to; but as it is too complicated to be wholly understood from the verbal description, without greater attention than ordinary readers are disposed to give, our draughtsman has prepared two figures, viz. a vertical section, Plate CXXXII. Fig. 9, and a horizontal section, Fig. 8, from the inventor's description, which, except the letters of reference, is as follows: The external shape of the submarine vessel bore some resemblance to two upper tortoise shells of equal size joined together, the place of entrance into the vessel being represented at A, Fig. 9, by the opening made by the swell of the shells at the head of the animal. The inside was capable of containing the operator, and air sufficient to support him thirty minutes without receiving fresh air. At the bottom B, opposite to the entrance, was fixed a quantity of lead for ballast. At one edge, which was directed before the operator, who sat upright, was an oar D, for rowing forward or backward. At the other edge was a rudder E for steering. An aperture at the bottom, with its valve a, was designed, to admit water for the purpose of descending; and two brass forcing pumps b, b', served to eject the water within when necessary for ascending. At the top, there was likewise an oar F for ascending or descending, or continuing at any particular depth. A water gauge, or barometer d, determined the depth of descent, a compass directed the course, and a ventilator within supplied the vessel with fresh air when on the surface. The internal shape of the vessel in every possible section of it, verged towards an ellipsis as nearly as the design would allow; but every horizontal section, see Fig. 8, although elliptical, yet came as near to a circle as could be admitted. The body of the vessel was made exceedingly strong; and to strengthen it as much as possible, a firm piece of wood H was framed parallel to the conjugate diameter, to prevent the sides from yielding to the great pressure of the incumbent water in a deep immersion. This piece of wood was also a seat for the operator. The entrance at A into the vessel was elliptical, and so small as barely to admit a person. This entrance was surrounded with a broad elliptical iron band ee, the lower edge of which was let into the wood, of which the body of the vessel was made, in such a manner, as to give its utmost support to the body of the vessel against the pressure of the water. Above the upper edge of this iron band, there was a brass crown, or cover G, resembling a hat with its crown and brim, which shut watertight upon the iron band ee. The crown was hung to the iron band with hinges, so as to turn over sidewise when opened. To make it perfectly secure when shut, it might be screwed down upon the band by the operator, or by a person without.

There were in the brass crown three round doors, one at f directly in front, and one at g on each side, large enough to put the hand through. When open, they admitted fresh air. Their shutters were ground perfectly tight into their places with emery, hung with
Diving.

Fig. 8.

The vessel was chiefly ballasted with lead fixed to its bottom B. When this was not sufficient, a quantity was fixed within at R, more or less according to the weight of the operator. Its ballast made it so stiff, that there was no danger of oversetting. The vessel with all its appendages, and the operator, was of sufficient weight to settle it very low in the water. About 200 pounds of the lead B at the bottom for ballast, could be let down forty or fifty feet below the vessel. This enabled the operator to rise instantly to the surface of the water, in case of accident.

When the operator would descend, he placed his foot upon the top of a brass valve a, depressing it by which he opened a large aperture in the bottom of the vessel, through which the water entered at his pleasure. When he had admitted a sufficient quantity, he descended very gradually. If he admitted too much, he ejected as much as was necessary to obtain an equilibrium by the two brass forcing pumps l, j, which were placed at each hand, as shown in Fig. 8. Whenever the vessel leaked, or he would ascend to the surface, he also made use of these forcing pumps. When the skilful operator had obtained an equilibrium, he could row upward or downward, or continue at any particular depth.

With an oar F placed near the top of the vessel, formed upon the principle of the screw, the axis of the oar entering the vessel, by turning the oar one way he raised the vessel, by turning it the other way he depressed it.

A glass tube d, 18 inches long, and 1 inch in diameter, standing upright, its upper end closed, and its lower end, which was open, screwed into a brass pipe, through which the external water had a passage into the glass tube, served as a water gauge or barometer to show the depth of water. There was a piece of cork, with phosphorus on it, put into the water gauge. When the vessel descended, the water rose in the water gauge, condensing the air within, and bearing the cork, with its phosphorus, on its surface. By the light of the phosphorus, the ascent of the water in the gauge was rendered visible, and the depth of the vessel under water ascertained by a graduated line. An oar D, formed upon the principle of the screw, was fixed in the fore part of the vessel. Its axis entered the vessel, and being turned one way rowed the vessel forward, but being turned the other way rowed it backward. It was made to be turned by the hand or foot.

A rudder E, hung to the hinder part of the vessel, commanded it with the greatest ease. The rudder was made very elastic, and might be used for rowing forward. The tiller m was within the vessel at the operator's right hand, and passing behind him, was fixed at a right angle on an iron rod, or spindle n, Fig. 8, which passed through the side of the vessel. The rod had a crank on its outside end, which commanded the rudder by means of a rod o, extending from the end of the crank to a kind of tiller fixed upon the left hand of the rudder. Raising and depressing the first-mentioned tiller m, turned the rudder as the case required.

A compass, marked with phosphorus, directed the course both above and under the water, and a line and lead sounded the depth when necessary.

Every opening was well secured. The pumps b, b had two sets of valves. The aperture a at the bottom for admitting water, was covered with a plate, perforated full of holes to receive the water, and prevent any thing from choking the passage, or stopping the valve from shutting. The brass valve might likewise be forced into its place with a screw if necessary. The air pipes i had a kind of hollow sphere fixed round the top of each, to secure the air pipes' valves from injury. These hollow spheres were perforated full of holes, for the passage of the air through the pipes. Within the air pipes were shutters to secure them, should any accident happen to the pipes, or the valves on their tops. Wherever the external apparatus passed through the body of the vessel, the joints were round, and formed by brass pipes, which were driven into the wood of the vessel; the holes through the pipes were very exactly made, and the iron rods which passed through them were turned in a lathe to fit them; the joints were also kept full of oil, to prevent rust and leaking. Particular attention was given, to bring every part necessary for performing the operations, both within and without the vessel, before the operator, and as conveniently as could be devised, so that every thing might be found in the dark, except the water gauge and the compass, which were visible by the light of the phosphorus; and nothing required the operator to turn to the right hand or to the left to perform any thing necessary.

The inventor then gives the following description of Powder magazine and its appendages, designed to be convey-

made by the submarine vessel to the bottom of a ship.

In the fore part of the brim of the crown G of the submarine vessel was a socket, and an iron tube dotted at h (Fig. 9.) passing through the socket. The tube stood upright, and could slide up and down in the socket six inches. At the top of the tube was a screw dotted at x, properly formed for entering wood, fixed by means of a rod which passed through the tube h, and screwed the wood screw fast upon the top of the tube. By pushing the wood screw up against the bottom of the ship, and turning it at the same time, it would enter the planks. Driving would also answer the same purpose. When the wood screw was firmly fixed, it could be cast off, by unscrewing the rod which fastened it upon the top of the tube.

Behind the submarine vessel, was a place above the rudder E for carrying a large powder magazine. This was made of two pieces of oak timber, large enough, when hollowed out, to contain 150 pounds of powder, with the apparatus used in firing it, and was secured in its place by a screw turned by the operator. A strong piece of rope extended from the magazine to the wood screw above mentioned, and was fastened to both. When the wood screw was fixed, and to be cast off from its tube, the magazine was to be cast off likewise by unscrewing it, leaving it hanging to the wood screw. It was lighter than the water, that it might rise up against the object to which the wood screw and itself were fastened.

Within the magazine was an apparatus, constructed to run any proposed length of time under twelve hours. When it had run out its time, it unpinioned a strong lock resembling a gun lock, which gave fire to the pow-
Diving.

This apparatus was so pinioned, that it could not possibly move till by casting off the magazine from the vessel it was set in motion.

The skilful operator could swim so low on the surface of the water, as to approach very near a ship in the night without fear of being discovered, and might, if he chose, approach the stem or stern above water with very little danger. He could sink very quickly, keep at any depth he pleased, and row a great distance in any direction he desired, without coming to the surface; and when he rose to the surface, he could soon obtain a fresh supply of air, when, if necessary, he might descend again, and pursue his course. The above vessel, magazine, &c. were projected in the year 1771, but not completed until the year 1775.

The ingenious writer then details the following experiments which he made, to prove the nature and use of a submarine vessel for destroying shipping.

The first experiment I made was with about two ounces of gunpowder, which I exploded 4 feet under water, to prove to some of the first personages in Connecticut that powder would take fire under water.

The second experiment was made with two pounds of powder, inclosed in a wooden bottle, and fixed under a hogshead, with a two inch oak plank between the hogshead and the powder. The hogshead was loaded with stones as deep as it could swim. A wooden pipe descending through the lower head of the hogshead, and through the plank into the powder contained in the bottle, was primed with powder. A match then put to the priming exploded the powder, which produced a very great effect, rending the plank into pieces, demolishing the hogshead, and casting the stones, and the ruins of the hogshead, with a body of water, many feet into the air, to the astonishment of the spectators. This experiment was likewise made for the satisfaction of the gentlemen above mentioned.

The inventor afterwards made many experiments of a similar nature, some of them with large quantities of powder. They produced very violent explosions, much more than sufficient for any purpose he had in view.

In the first essays, with the submarine vessel, Mr Bushnell took care to prove its strength to sustain the great pressure of the incumbent water, when sunk deep, before he trusted any person to descend much below the surface, and he never suffered any person to go under water, without having a strong piece of rigging made fast to it, until he found him well acquainted with the operation necessary for his safety. After that he made him descend and continue at particular depths, without rising or sinking, row by the compass, approach a vessel, go under her, and fix the wood screw, mentioned above, and dotted at b, in Fig. 9, into her bottom, &c. until he thought him sufficiently expert to put his design into execution.

He found, agreeable to his expectations, that it required many trials to make a person of common ingenuity a skilful operator. The first he employed was very ingenious, and made himself master of the business; but was taken sick, in the campaign of 1776, at New York, before he had an opportunity to make use of his skill, and never recovered his health sufficiently afterwards.

After various attempts to find an operator to his wish, the inventor sent one who appeared more expert than the rest, from New York, to a fifty gun ship, lying not far from Governor's Island. He went under ship, and attempted to fix the wooden screw into her bottom, but struck, as he supposes, a bar of iron which passes from the rudder hinges, and is spiked under the ship's quarter. Had he moved a few inches, which he might have done without rowing, I have no doubt but he would have found wood where he might have fixed the screw, or if the ship were sheathed with copper, he might easily have pierced it; but not being well skilled in the management of the vessel, in attempting to move to another place, he lost the ship.

After seeking her in vain for some time, he rowed some distance, and rose to the surface of the water, but found day light had advanced so far that he durst not renew the attempt. He says that he could easily have fastened the magazine under the stern of the ship above water, as he rowed up to the stern and touched it before he descended. Had he fastened it there, the explosion of one hundred and fifty pounds of powder, (the quantity contained in the magazine,) must have been fatal to the ship. In his return from the ship to New York, he passed near Governor's Island, and thought he was discovered by the enemy on the island. Being in haste to avoid the danger which he dreaded, he cast off the magazine, as he imagined it retarded him in the swell, which was very considerable. After the magazine had been cast off one hour, the time the internal apparatus was set to run, it blew up with great violence.

Afterwards, there were two attempts made in Hudson's River, above the city, but they effected nothing. One of them was by the abovementioned person. In going towards the ship, he lost sight of her, and went a great distance beyond her, and when he at length found her, the tide ran so strong, that as he descended under water for the ship's bottom, it swept him away. Soon after this the enemy went up the river, and pursued the boat which had the sub-marine vessel on board, and sunk it with their shot. Though Mr Bushnell afterwards recovered the vessel, he says he found it impossible at that time to prosecute the design any farther. Having been in a bad state of health from the beginning of his undertaking, and being then very unwell, the situation of public affairs became such that he despaired of obtaining the public attention, and the assistance necessary to support himself, and the persons he must have employed, had he proceeded. Besides, he found it absolutely necessary that the operators should acquire more skill in the management of the vessel, before he could expect success, which would have taken up some time, and made no small additional expense; he therefore gave over the pursuit for that time, and waited for a more favourable opportunity, which never arrived.

The art of diving has been carried to a great degree of perfection by Mr Braithwaite, who has for many years past made it a profession to search for valuable wrecks, and in this has been exceedingly successful. His great undertaking was the wreck of the Abergavenny East India ship, which was lost off Weymouth. From this, at a depth of ten fathoms, he recovered all the most valuable property, cutting through the deck, where he wished to enter, by saws and instruments worked by the people above, and directed by himself. We have been informed that he somehow obtained the diving bell, made by himself, and at others in the apparatus we have before described as the invention of Mr Tonkin. Mr Braithwaite's practical acquaintance with all kinds of hydraulic machinery, which he is constantly making for the great London breweries, gives him great advantages in these pursuits, by enabling him to contrive quickly and construct any apparatus which the work requires. See the references at the end of Divining Bell. (J. F.)
DIVING BELL.

DIVING BELL, a chest or tub, usually of a conical shape, beneath which, when inverted, divers may descend to very considerable depths under water; and though the bell is open at bottom, the air it contains prevents the water filling it, because the air cannot escape from the top of the vessel. At the same time, through the open bottom they can gain access without any obstruction to whatever they may find; and this circumstance gives the diving bell a great advantage over any other contrivance for the same purpose. Most of the successful enterprises in diving for shipwrecked treasures, have been carried into effect by the assistance of the diving bell, in preference to any other contrivance; because in it the divers have room to move, and act with perfect freedom, to employ tools for breaking into ships, removing stones, &c. They can descend two, three, or more in a company, if they wish to accomplish any great object at the bottom of the sea. It is also a great advantage, that they can carry down lights, which though not absolutely necessary, are very useful in discovering the object of the diver's search. Lastly, the bell will admit of diving in greater depths than any other method, and of a longer continuance at the bottom.

The usual construction for a diving bell, is that of a cask or tub of wood, in the form of a truncated cone, the base being open, and the smaller end well closed, as every part must be at its joints, and strongly bound by hoops on the outside. It is poised by lead weights, attached to it round the open end, till it will sink with the open end downwards, when full of air, and is so suspended by a rope, that it will descend in a perpendicular direction and no other, that the open end or lower edge of the bell may close upon the surface of the water all round at once. Seats are fixed on the inside for the divers to sit upon when they are let down into the water, beneath the shelter of the bell, from which the air cannot escape, because it is made tight in all parts except the bottom, and to get out there it must first descend beneath the surface of the water, in the bell, which will be considerably above the lower edge; for as the bell descends, the pressure of the water upon the included air compresses it into a smaller space than it before occupied, and this condensation increases with the depth from the surface, according to the weight of water acting upon it. At thirty-three feet deep, the air will be condensed into half the space, and the bell will therefore be half full of water, and the air will have an elastic pressure of two atmospheres. A man will not experience any great inconvenience from being a short time confined in such condensed air, because it is taken in by the breath, and soon insinuating itself into all the cavities of the body, has no sensible effect, provided the bell is allowed to descend slowly, to give time for that purpose. When the bell is let down suddenly, a pressure is first felt on each ear, which, by degrees, grows painful, as if a quill were forcibly thrust into the hole of the ear; but as the condensed air gains admission by degrees into the internal cavities of the ear, the pain ceases. When the bell is drawn up, the condensed air finds much easier passage from those cavities, without occasioning any pain. The force thus exerted upon the auditory passages might be expected to be prejudicial to the hearing, but experience shews that this is not the case.

A real inconvenience is experienced from the diminished capacity of the bell, which becomes filled with water, in proportion to the depth. Hence the space occupied by the air in the upper part of the bell will bear the same proportion to the lower part of it, which is filled with water, as thirty-three feet does to the depth from the bell to the surface; therefore, if the bell is at thirty-three feet depth, the two will be equal, consequently the bell will be half full of water, when the air, being crowded into such a small space, will soon become heated, and unfit for respiration, and the bell must be drawn up to recruit it, not to mention the unpleasant situation of the diver, who must be almost covered with water in the bell, and will not be able to endure the cold and pressure of the water. Respecting the air, it has been estimated, that a man can subsist an hour in a bell containing a ton, when at a depth of thirty or thirty-five feet.

This simple diving bell, which, from the defects above stated, is not applicable for diving in deep water, is by no means a modern invention. Aristotle speaks of a kind of kettle, used by divers, to enable them to remain for some time under water, but does not clearly describe the manner in which they were used. Professor Beckman informs us, that the earliest mention of the use of the diving bell in Europe, is that of John Taisnier, who was born in Hainault in 1509, and had a place at court under Charles V. whom he attended on his voyage to Africa. He relates, in what manner he saw, at Toledo, in the presence of the emperor and several thousand spectators, two Greeks let themselves down under water, in a large inverted kettle with a burning light, and rise up again, without being wet. It appears that this art was then new to the emperor, and the Spaniards, and that the Greeks were requested to make the experiment, in order to prove the possibility of it.

In an old book on fortification, by Lorini, he describes a diving machine, consisting of a square box, bound round with iron, and furnished with windows; it has a stool affixed in it for the diver. The contrivance is probably older than this Italian writer, as he does not pretend to be the inventor of it. From this time the diving bell was frequently employed to recover valuable wrecks, but from the defects above described, it could not be used in great depths. It was not until Dr Halley began his experiments, that adequate remedies were provided. This ingenious philosopher invented means to convey air down to the diving bell, whereby not only the included air is renewed for breathing, but the whole of the water is kept out from the bell, whatever the depth may be, and air may be furnished in any desired quantity. He describes his apparatus in the following manner, in the Philosophical Transactions:

"The bell I made use of was of wood, containing about sixty cubic feet in its concavity, and was of the form of a truncated cone, whose diameter at top was three feet, and at bottom five; this I coated with lead, so heavy that it would sink empty, and distributed its weight about its bottom, so that it would go down in a perpendicular situation, and no other; in the top I fixed a strong but clear glass, to let in the light from above, and likewise a cock to let out the hot air that had been breathed; and below, about the hinder part under the bell, I placed a stage, which hung by three ropes, each of which was charged with about one hundred weight, to keep it steady. This machine I suspended from the mast of a ship by a spreit, which was sufficiently secured by stays to the mast head, and was directed by braces to carry it over board, clear of the ship's side, and bring it again within board.

To supply air to this bell, when under water, I air barrels caused a couple of barrels, of about thirty-six gallons.
Diving Bell.

each, to be cas'd with lead, so as to sink empty, each having a bung hole in its lowest part, to let in water as the air in them condensed, on their descent, and to let it out again, when they were drawn up full of water from below, and to a hole in the uppermost part of these barrels I fixed a leathern trunk, or hose, well liquored with bees wax and oil, and long enough to fall below the bung hole, being kept down by a weight appended, so that the air in the upper part of the barrels could not escape, unless the lower ends of these hose were first lifted up.

I fitted these air barrels with tackle proper to make them rise and fall alternately, after the manner of two buckets in a well, which was done with so much ease, that two men with less than half their strength could perform all the labour; and in their descent, they were directed by lines fastened to the under edge of the bell, which passed through rings placed on both sides the leathern horse of each barrel, so that sliding down by those lines, they came readily to the hand of a man who stood on the stage to receive them, and to take up the ends of the hose into the bell. Through these hose, as soon as the ends of the pipes came above the surface of the water, in the barrels, all the air that was included in the upper parts of them, was blown with great force into the bell, whilst the water entered at the bung holes below, and filled them. As soon as the air of one barrel had been thus received, upon a signal given it was drawn up, and at the same time the other descended; thus, by an alternate succession, furnishing air so quick, and in such plenty, that I myself have been one of five who have been together at the bottom, in nine or ten fathoms water, for above an hour and a half at a time, without any sort of ill consequence; and I might have continued there as long as I pleased, for anything that appeared to the contrary. Besides the whole cavity of the bell was kept entirely free from water, so that I sat on a bench which was diametrically placed near the bottom, with all my clothes on; I only observed that it was necessary to let down gradually at first, as about 12 feet at a time, and then to stop and drive out the water that entered, by receiving or four barrels of fresh air, before I descended farther; but being arrived at the depth desired, I then let out as much of the hot air that had been breathed, as each barrel would replenish with cool, by means of the cock at the top of the bell, through whose aperture, though very small, the air would rush with so great violence, as to make the surface of the sea boil, and to cover it with a white foam, notwithstanding the great weight of water over us.

Thus I found I could do any thing that was required to be done just under us, and that by taking off the stage, I could, for a space as wide as the circuit of the bell, lay the bottom of the sea so far dry, as not to be over shoes thereon; and, by the glass window, so much light was transmitted, that when the sea was clear, and especially when the sun shone, I could see perfectly well to write or read, much more to take up any thing that was under us; and, by the returns of the air barrels, I often sent up orders, written with an iron pen, on small plates of lead, directing how to move us from place to place; at other times, when the water was troubled and thick, it would be as dark as night below; but in such a case I have been able to keep a candle burning in the bell as long as I pleased, notwithstanding the great ex pense of air requisite to maintain flame.

I take this invention to be applicable to various uses such as fishing for pearls, diving for coral, sponges and the like, in far greater depths than has hitherto been thought possible; also for the sitting and plain ing of the foundation of mole{s}, bridges, &c. upon rocky bottoms, and for the cleaning and scrabbling of ships' bottoms, when foul, in calm weather at sea.

It was by this contrivance of Dr Halley's to send down fresh air to the diving bell, that it was rendered a useful and practicable mode of recovering treasures at considerable depths. In other situations it had before been successfully employed. In a work printed at Rotterdam in 1689, and entitled G. Sinclairi Ars nova et Magna Graevitatis et Lenitatis, there is given an account of a kind of diving bell, used by a person who recovered some cannon from the wrecks of several ships of the celebrated Spanish Armada, which were sunk on the western coast of Scotland near the Isle of Mull, just after the English had dispersed them in the channel in 1588. The report of the riches they contained was a constant excitement to speculative to recover the treasure, and many attempts were made, without success. The person who made the preceding attempt did not recover sufficient to defray his expenses.

William Phipps, a native of America, submitted a project to King Charles II. in 1680, for searching and unloading a rich Spanish ship, sunk on the coast of Hispaniola. He represented his plan so plausibly, that the king gave him the command of a ship, and furnished him with every thing necessary for the undertaking. He set sail in the year 1683, but being unsuccessful, returned again in great poverty, though with a firm conviction of the practicability of his scheme. By a subscription promoted chiefly by the Duke of Albemarle, the son of the celebrated Monk, Phipps was enabled, in 1687, to try his fortune once more, having previously engaged to divide the profit, according to the 26 shares of which the subscription consisted. At first all his labour proved fruitless; but at last, when his patience was almost exhausted, he was so lucky as to bring up, from the depth of six or seven fathoms, so much treasure, that he returned to England with the value of £200,000 sterling. Of this sum he himself got about £16,000, others say £20,000, and the Duke £90,000. After he came home to speak of his experience and success, the king was induced to use his influence with the Lords of the Trinity House, and to make the necessary steps to enable the new comers to seize both the ship and the cargo, under a pretence that Phipps, when he solicited for his majesty's permission, had not given accurate information respecting the business; but the king answered, with much greatness of mind, that he knew Phipps to be an honest man, and that he and his friends should share the whole among them had he returned with double the value. His majesty even conferred upon him the honour of knighthood, to show how much he was satisfied with his conduct. The construction of Phipps's apparatus is not known.

In 1791, soon after Dr Halley made the descent above related, he invented additional apparatus to enable the diver to go out from the bell to a considerable distance, and stay a sufficient time in the sea, and walk about on the bottom, with full freedom to act as occasion required. Considering that the pressure being greater on the surface of the water in the bell, than on any other surface which was higher than that in the bell, the air would pass by a pipe from the bell into any cavity for air; where the surface of the water was higher, he concluded, that a man by putting on his head a bell or cap of lead, made sufficiently heavy to sink empty, and in form resembling the bell itself, might keep his head dry, and might receive a constant stream of air from the great bell, so long as the surface of the
water in the cap was above the level of that in the bell, by means of a flexible pipe which he could carry coiled on his arm.

In pursuance of this idea, he procured pipes to be made, which answered all that was expected from them. They were secured against the pressure of the water by a spiral brass wire, which kept them open from end to end, the diameter of the cavity being about the sixth part of an inch. These wires being coiled with thin glove leather, and neatly sewed, were dipped into a mixture of hot oil and bees wax, which, filling up the pores of the leather, made it impenetrable to water; several thicknesses of sheep’s entrails were then drawn over them, which, when dry, were covered with paint, and then the whole defended with another coat of leather to keep them from fretting. Several of the pipes were as much as forty feet long, the size of a half inch rope; one end of a pipe being fixed in the bell at some height above the water, the other end was fastened to a cock which opened into the cap. The use of the cock was to stop the return of the air whenever there was occasion to stoop down or go below the surface of the air in the bell, which occurred as often as there was occasion to go out or return into the machine. The diver, therefore, when he has descended to the bottom in the great bell, puts on his cap with the pipe hanging on his arm like a coil of rope. As soon as he leaves the bell, he opens the cock in the pipe, and walks on the bottom of the sea, giving out the coils of his pipe as it is required; and this serves as a clue to direct him back again to the great bell, from whence he derives his supply of air by means of the pipe.

The weight of a man being very little more than that of his bulk in water, he could not act with any strength, nor stand with any firmness, especially if there is any current, without a considerable addition of weight; the leaden caps were therefore made to weigh about half a hundred weight, to which was added a girdle for the waist, formed of large weights of lead nearly of as great weight in the whole; also two clogs of lead for the feet of about 12 pound each. With this accession of weight, Dr Halley found a man could stand well in an ordinary stream, and even go against it. It is necessary for the diver to be provided against the cold of the water, which, though it could not be removed so that a man could endure it long, yet it was much eased, by wearing a waistcoat and drawers made close to the body, of that thick woollen stuff of which blankets are made; this becoming full of water, would be a little warmed by the heat of the body, and keep off the chill of new cold water coming on.

When the water is not turbid, things are seen sufficiently distinct at the bottom of the sea; but a small degree of thickness makes perfect night in a moderate depth of water. To obtain an open view from the leaden caps, which, from their use, the Doctor called caps of maintenance, he at first used a plain glass before the eyes, but soon found that the vapour of the breathing obstructed such a view of the surface of the glass, that it lost its transparency; to remedy this, he found it necessary to prolong that side of the cap which was before the eyes, and thereby enlarge the prospect of what was beneath.

Mr Martin Triewald, who was military architect to the king of Sweden, proposed another form of the diving-bell adapted for a single diver, which, being on a small scale, may be made at a less expense than Dr Halley’s, and drawn up with more convenience. It is represented in Fig. 8. Plate CXXXI. The bell AB is made of thin copper plate, tinned on the inside, and strengthened without by bands of iron hoop arranged in different directions. It is suspended by a rope C, from the ring A at the top, and caused to sink perpendicularly by weights DD suspended from the bottom hoop, as well as by a large iron ring or plate E, which is suspended at such a distance from the bottom of the bell by chains, that when the diver stands upright with his feet upon this plate, his head is above the water in the bell. This situation is better than if his head was in the top part A of the bell, the air being cooler and more pure near the surface of the water than higher up, because the air which has been breathed is heated, and rises up to the top; but when it is necessary for the diver to rise up into the top of the bell, the inventor has provided him the means of drawing up the cool air from the bottom near the water. This is a spiral copper tube, shown by the dotted lines b c. It is placed round the inside of the bell, the lower end opening in the bottom of the bell, and the upper end provided with a flexible leather tube ending in an ivory mouth-piece d, for the diver to hold in his mouth and inspire the air from below; whilst at every expiration he throws out the air through his nostrils into the upper part of the bell. This bell may be supplied with fresh air from barrels in the same manner as Dr Halley’s; and is therefore provided with a cock in the top to allow the impure air to escape when a fresh supply is obtained. It is illuminated by four strong lenses in the top, at GGG, each provided with copper shutters, to defend them from accidents when on shore.

Several important improvements were made in the diving bell in 1776, by Mr Spalding of Edinburgh, for whom the Society of Arts presented a reward for the invention. This gentleman had in the two preceding years, acquired considerable experience in the management of a bell on Dr Halley’s plan, which he had constructed, in the hopes of recovering some of a considerable property which was lost in a ship that was wrecked on the Scars, or Fern Islands, in 1774, in the night, when all the crew perished. Some of the light goods were thrown on shore; and it was proposed to recover the rest by diving, the remainder of the owners giving up the management of the whole to Mr Spalding. His first experiments were made in depths of 5, 6, and 8 fathoms in Leith roads; and having in these made his apparatus tolerably perfect, he sailed for Dunbar, thirty miles distance, in an open long boat, sloop rigged, and of about six or eight tons burthen. By a mistaken account, he had been informed the bottom of the Fox ship of war lay there; but upon his arrival, the oldest seaman in the place could give him no intelligence, as that vessel perished in the night, with all on board, somewhere in Dunbar bay, and by storms, during so long a period as thirty years, was thought to be drenched. In order to gratify the curiosity of some friends there, he still determined to descend where it might be thought probable her bottom lay; but in seven and eight fathoms water found nothing but a hard sandy bottom, from whence he was led to conjecture, that the proprietors of the valuable effects which were on board that vessel, might have found their account in sweeping for her. Being informed that a vessel, which was thrown up by accident in the river Tay, near Dundee, with a large quantity of iron, lay within two fathoms of the surface at low water, he determined to make trial there, and accordingly sailed across the Frith to that place; about fifteen leagues distant from Dunbar. Here he went down three different times, changing the
ground at each going down, and at last fell in with a
stump of the wreck, sunk five fathoms deep at low wa-
ter to a level with the soft bed of the river, which is
composed of a light sand intermixed with shells. The
principal parts of this wreck were supposed to have been
carried away by an immense body of ice the year be-
fore. He found, that the mudliness of the river oc-
casions a darkness at only two fathoms from the surface
that cannot be described; and from the smallness of
his machine, which contained only forty-eight English
gallons, it was impossible to have a candle burning in
it, which would consume the air too quickly for any
man to be able to work, and at the same time pay at-
tention to recovering the necessary supplies of air.

These trials were only preparatory to his views at
the Scares, hoping to acquire experience, which would
enable him to surmount the dangerous difficulty of the
unequal rocky bottom which he expected to meet with;
but in the preceding trials, and different alterations of
the machinery, so much time had been lost, that the
weather became stormy, and he was obliged to wait at
Bamborough Castle some time, till the weather became
more favourable. He then sailed to the Scares, with his
brother, three sailors, and two pilots. It was four in the
afternoon, about high water, when he went down at
a small distance from the place, where he judged
the wreck to lie. The depth was about ten fathoms.

He fortunately alighted on a flat part of the
rock, within a small space of a dreadful chasm, and had
just gone two steps with his machine, when the terror
of the two pilots was so great, that, in spite of his bro-
ther, they brought him up very precipitately, before he
had in any degree examined around him. On coming
into the boat, they remonstrated on the danger of the
machine being overturned either on the wreck or the
rocks, and also on the impossibility of raising any of
the weighty goods with so small a purchase in an open
boat, and in a place where, at this season, no large
vessel would venture to lie, as the nights were then so
long, and only two passages for a small vessel to run
through, in case of a gale of easterly or southerly wind;
one of the passages being extremely narrow, and both
of them dangerous.

Convinced from this, says Mr Spalding in his ac-
count, ‘that with an open boat nothing could be ac-
complished, and that, except in June and July, no
man would risk himself with me in a sloop, to continue a
few days and nights at anchor there, I was obliged to
abandon my project; yet I determined to take a view
of the guns of a Dutch ship of war lost in the year
1704, and as they lay two or three miles nearer the
land, I could execute this design with less difficulty,
especially as the weather continued still favourable.
Having procured all the intelligence possible, we went
to the place, where I went down four different times,
but could find no marks of any wreck, notwithstanding
my walking about in five and six fathoms water, as far
as it was thought safe to allow the rope to the bell,
continuing generally twenty minutes each time at the
bottom. On this occasion I was obliged to carry a cutting
hook and knife, and clear away the sea weeds, which at
this place are very thick and strong; without this me-
thod I could not move about. At the fifth going down,
each trial being in a different place, I was agreeably
surprised to find a large groove of tall weeds, all of them
from six to eight feet high, with large tufted tops, mostly
in regular ranges, as far as the eye could reach, a
variety of small lobsters and other shell fish swimming
about in the intervals." He then discovered the place
where one of the cannons lay; but was too much ex-
hausted, by having been down at intervals for near
three hours, to attempt bringing it up.

In these descents, Mr Spalding found out two very
serious dangers attendant on the use of the bell, in Dr
Halley’s plan. These are, First, by Dr Halley’s construc-
tion, the sinking or rising of the bell depends entirely
upon the people who are at the surface of the water;
and as the bell, even when in the water, has a very
considerable weight, the raising of it not only requires
a great deal of labour, but there is a possibility of the
rope by which it is raised breaking; and this every
person in the bell would inevitably perish. Secondly,
As there are, in many places of the sea, rocks which
lie at a considerable depth, the figure of which cannot
be perceived from above, there is danger that
some of their ragged prominences may catch hold of
one of the edges of the bell in its descent, and thus over-
set it before any signal can be given to those above,
which would infallibly be attended with the destruction
of the people in the bell, especially as it must always
be unknown before trial what kind of a bottom the sea
has in any place.

Mr Spalding made such additions to Dr Halley’s bell
as completely obviated these defects. They will be ren-
cered evident from the following description: ABCD,
Fig. 6, is the body of the bell, made of pipe staves, five
feet long, five feet diameter at bottom, and two and a
half at top. It is suspended by four ropes e, e, attach-
ed to hooks, fastened on the sides of the bell, and meet-
ning at the top where the hook of the great rope Q takes
them. e, e, are the ballast weights, suspended from
hooks on the outsides. These keep the mouth of the
bell always parallel to the surface of the water, whether
the machine, taken all together, is lighter or heavier
than an equal bulk of the fluid. By these weights alone,
however, the bell would not sink; another is there-
fore added, represented at L, and which can be raised
or lowered at pleasure, by means of a rope passing over
the pulley a, and fastened to one of the sides of the bell
at M. As the bell descends, this weight, called by Mr
Spalding the balance weight, hangs down a consider-
able way below the edge of the bell. In case the edge
of the bell is caught by any obstacle, the balance weight
is immediately lowered down, so that it may rest upon
the bottom. By this means the bell is lightened, so that
all danger of oversetting is removed; for being lighter
without the balance weight than an equal bulk of wa-
ter, it is evident that the bell will rise as far as the
length of rope affixed to the balance weight will allow
it. This weight, therefore, will serve as a kind of an-
cchor to keep the bell at any particular depth which the
divers may think necessary; for being let down to the
bottom before the bell descends, the diver by hauling
the rope will descend, though he does not raise the
weight. Instead of wooden seats or stage used by Dr
Halley, Mr Spalding made use of ropes, suspended by
hooks b, b across the bottom of the bell; and on these
ropes the divers may stand without any inconvenience.
Two windows, made of thick strong glass, are fixed near
the top of the bell, for admitting light to the divers.
T, N represent the two air casks, with their tackle; and
OCP the flexible pipe, through which the air is ad-
mitted to the bell: the casks contain 40 gallons each.
In the ascent and descent of this cask, the end of the pipe
is guided by the lines M, extended from the bell to the
ship above. The ends of the pipes are kept down by
a small weight appended, as in Dr Halley’s machine;
or what is better, they may have cocks as at P. R is a
DIVING BELL.

Diving Bell. cock, by which the hot air is discharged as often as it becomes troublesome, and a fresh supply is obtained from the air casks.

Spalding's double bell. By another very ingenious contrivance, Mr Spalding rendered it possible for the divers to raise the bell, with all the weights appended to it, even to the surface, or to stop at any particular depth as they think proper, and thus they could still be safe even though the rope designed for pulling up the bell was broke. This was accomplished, by affixing a second bell of smaller dimensions over the large one, as shown at S, being fixed thereto by screws at different places as well as by the ropes c, e, which suspend the bell. It contains 25 gallons. In the top of it is a cock t, which can be opened by the diver, to permit the air to escape from the upper bell. Its handle comes down through the great bell through the top at t. There is also another cock at v in the top, which permits the air to pass out of the great bell, and rise into the small one. There is so much space left between the two bells, that the water has free entrance into the upper as well as into the lower one. When the bell is first let down the cock t in the top of the upper one is opened, and therefore the air escapes from it, and the water enters till it is full. In this state the bell is, as before mentioned, lighter than an equal bulk of water without the balance weight, though with the addition of that it is heavier. Now if the divers wish to raise themselves, they turn the small cock v, by which a communication is made between the bells. The consequence of this is, that a quantity of air immediately enters from the lower into the upper bell, and forces out a quantity of the water contained therein. The air, which is thus let out from the lower bell, must be immediately replaced from the air barrel, and thus renders the bell lighter, by the whole weight of the water which is discharged. The air is to be let out very slowly, otherwise the bell will rise to the top with so great velocity, that the divers will be in danger of being shaken out of their seats. The quantity let into the upper bell will determine the rate of its ascent. Thus, if a certain quantity of air is admitted into the upper cavity, the bell with the balance will descend very slowly; if a greater quantity, it will neither ascend nor descend, but remain stationary; and if a larger quantity of air is still admitted, it will rise to the top.

Indeed the bell would rise very slowly when the air is admitted, from the lower into the upper cavity, from another cause, independent of taking in any more air from the barrel. Thus the air in the great bell is condensed, by the pressure of a certain column of water. Now when a portion of the contained air is transferred to the upper bell, that quantity is pressed by a column of water of 5 or 6 feet less altitude than it was before, because the upper bell is that height above the other, consequently it will expand itself, and displace rather a greater quantity of water from the upper bell than its absence from the lower one admits into it.

By following these directions, every accident may be prevented, and people may descend to great depths without the least apprehension of danger. The bell also becomes so easily manageable in the water, that it may be conducted from one place to another by a small boat with the greatest ease, and with perfect safety to those who are in it.

We consider Mr Spalding's form of the diving-bell as the best adapted of any which has been yet made public for descending deep into the sea. It may be made of one single cask instead of two. In this case, it must have a false bottom, to divide it into two cavities, the air being allowed free entrance into the lower part of the upper one, through a number of auger holes bored through the staves, close above the partition. The inventor's reason for making them separate, was, that he might disencumber his bell of the small one when he did not think it necessary to employ it.

The writer of this article having had occasion to consider the best means of diving to a wrecked ship, in a considerable depth of water, conceived a very material improvement upon Mr Spalding's plan, of dividing the bell into two cavities, so that it can at all times be made heavier or lighter, as the divers wish. At the same time, he drew up a plan for such a system of tackle for the management of any kind of bell, either at sea or in a river, as would greatly facilitate its operation; for the success of diving, with any kind of bell, will greatly depend upon the convenience of its tackle, that it may be let down or drawn up, and removed in any direction on the bottom with the least possible loss of time; for as it is found injurious to divers to remain a long time in the condensed air when the depth is very great, if much time is expended in getting to the required situation, they will be unable to do anything before they find it necessary to return to the surface, to relieve themselves from the pressure. This improvement of the bell consists in making the upper chamber quite tight, and of considerable strength, having no openings to admit water as in Mr Spalding's machine. It is furnished on the under side with two small brass forcing pumps fixed in the partition which forms the chamber, and provided with proper valves and pistons, as well as levers with handles for the divers to work them by, and force air into the upper chamber from the bell. The valves of these pumps where they pass through the partition, will permit the air from the bell to enter the chamber when the pressure below is the greatest, but always prevent it from returning. There is a cock in the partition, to allow the air to descend at the pleasure of the diver. The action of this chamber is as follows: When the divers have descended to a certain depth and then stop, as Dr Halley describes, to have as much air as Mr Spalding's will supply them, the supply will be diminished by the compression of the contained air, they are to work these pumps, to condense as much as they can of the air into the upper chamber, having the quantity which is thus taken from the great bell immediately replenished from the air barrel. By repeating this every time they stop, and also when they arrive at the bottom, they obtain a store of fresh air in reserve for two purposes: First, if by any accident the air barrel, or any part of its tackle, should fail, and interrupt the supply of air, they can let out a quantity of air from the upper chamber, to serve them till the tackle is repaired, or till they can be drawn up. It also gives them the means of adjusting the weight of the bell in a more perfect manner than Mr Spalding's. Thus, if the ballast is so adjusted, that when the bell is full of air all but 6 inches of the lower part, its weight without the balance weight is rather lighter than water, so as just to rise but no more, the diver may manage to hold it down or descend, by pulling the balance weight rope with a very slight force. Now in this case, if they require to rise without the aid of those above, they open the cock, let out of the chamber as much air as will expel the water from the 6 inches of the lower part of the bell, and thus by displacing more water rendering it sufficiently buoyant to rise to the surface, and carry the balance weight up with it if required. They have,

Air vessel and pumps. Their use and action.
Defect of Spalding's Bell

The means of coming up at any time; whereas in Mr Spalding's bell, they can only take the opportunity of a cask of air being sent down, to introduce so much of air into the upper bell as will carry them up; and even this would be very dangerous to attempt, for a reason which the ingenious inventor seems to have overlooked. Thus suppose, when at the bottom in 66 feet water, the great bell is quite full of air at a pressure of three atmospheres. Now if the small bell is half filled with air, to give the buoyancy required to raise the bell, it will ascend, but at every foot of rise the pressure diminishes, and the air expands itself. That in the great bell escapes, by bubbling out under the bottom; but in the upper one it continues to displace more and more water, giving the bell an increasing power of ascent till at 33 feet depth, when it will have a pressure of only two atmospheres. The small bell will be quite full, thus giving to the bell a power of ascent twice as great as it began with, and producing an accelerated motion which the divers would find it difficult to control: for, though it might be done, by letting out the air from the upper bell by degrees, it would be hazardous, because if they once let out too much, so as to destroy the power of ascent, the bell would sink, and never have the means of rising again.

On the proposed plan with air pumps, this could never happen: for, if the divers found themselves too buoyant, they could by the pump return as much air into the chamber as would restore the equilibrium. Lastly, in Mr Spalding's, if they get any air into the upper chamber to give them a power of ascent, they depend altogether upon the exertions of the man who holds the balance weight rope to keep them down, and if this should break, they rise with a dangerous velocity.

This bell for diving to wrecks of ships, should be made to contain two persons. Its most convenient form will be that of the frustum of an elliptical cone; its base to be 6 feet by 4; the top 3 feet 6 inches by 2 feet 6 inches; and 6 feet 6 inches in height. If it is to have the air chamber formed by a partition in the top, to receive the air condensed by the pumps. As this vessel will require to be very strong, it would be best made of thick sheet copper, and fixed in the top of the bell against its crown, being rather smaller than the bell, and in the form of a hemisphere. It will leave a space all round, of a similar form to that of the bottom of a green glass bottle between it and the sides of the bell. By this means the vessel will not obstruct the light which enters at the windows, made round in the side of the bell at the top, or prevent it proceeding down to the divers. This space round the air vessel also receives the hot air which has been breathed; and the cock to let it off is in the very highest part. The pumps should have almost all the length of their barrels contained within the copper vessel, and should have proper levers, with handles to work them, situated conveniently within the diver's reach. As the bell requires to be loaded with a great weight, the best plan of all, where expence is not regarded, is to make the whole of cast iron, and then its strength will be much greater, and without any danger of leakage. The chamber in the top may then be cast in one piece with the crown. The windows should be convex lenses of glass, such as are now used in ships decks, being complete hemispheres on the outside, and plains on the side which is within. They concentrate the light from all directions, and throw it in the bell. The sides should be painted white within to reflect the light, and also on the outside, that it may be visible to those in the ship as long as possible when under water.

To find the direction in which they would be moved, the divers should have a compass hung up in the bell. The most convenient will be that kind, which captains of ships usually have hung from the ceiling of their cabins. The centre pin of the needle being fixed in the glass of the box, the card can be seen from beneath. It will be satisfactory to the divers to know at what depth they are from the surface; and for this purpose a gauge, represented in Fig. 6, should be fixed within the bell. It is a glass tube $a b$, hermetically sealed at the top, and at the bottom cemented into a metal tube $b$, which turning at right angles, has a screw to fix it into the side of the bell. To defend it from injury, the tube is bedded in a piece of board, which has divisions and feet marked upon it, to show how high the water rises in it; for it is by this that the depth or pressure is shewn, because the water entering freely into the lower end of the tube, condenses the air in the glass tube into a space proportional to the intensity of the pressure. Thus at 33 feet deep, the water will rise up half way to the top of the tube; at 66 feet two-thirds; at 93 three-fourths. It is, therefore, upon this principle that the divisions are made; or if any doubt is entertained as to the glass being perfectly cylindrical, it may be done by the experiment of letting down the bell to a known depth, and marking how high the water rises. The figures 1, 2, 3, &c. on the other side, opposite the several figures 33, 36, 93, &c. shew the compression of the air at those depths to be equal to 1, 2, or 3 atmospheres; or what is the same thing, that the air in the tube or in the bell is condensed into one-half, one-third, &c. of the space it occupied above. After all, this instrument is rather a matter of curiosity than utility, because should it be ever so accurately divided, the variations of the atmosphere will render it untrue; for if the air, with which the tube is filled before the descent, has a greater or less density, (as the barometer shews it has,) it will take more or less than 33 feet of water (the weight of which always continues the same) to condense the air into half the space: hence the scale will constantly vary.

The tackle proposed for suspending and managing the bell is as follows: If it is to be used at sea, it may be hung from the yard-arm of any ship which carries a square mainsail. The bell rope may pass through a block at the extremity of the yard; then being led through another block at the slings or middle of the yard, so as to come down close to the mast, it may be conducted by a match block on the deck, for the men to haul it by hand, or by the ship's windlass, though the capstan will be better if she has one. If there is a stream, the ship should be moved by the head with two cables at an angle, so that by taking up one, and giving out the other, she may be moved sidewise, to sweep the bell along the ground to search for any thing; or by taking up or giving out both at once, she will be moved in an opposite direction. When the place of the wreck is found, and it is only requisite to move it a few feet in the latter direction, it may be very conveniently done by braiding the yard, to carry it fore or aft by the same braces or tackles which are used in the sailing of the ship; and the bell rope being conducted down from the yard close to the mast, in the same manner as the topsail sheets are, it will neither be taken up or let down at all by this motion of the yard-arm from which the bell is suspended.

If there is a steady and moderate breeze, the ship may ride with one anchor, and shift her position by the sails and rudder to the required station. By their compass,
Diving Bell. divers find the direction in which they wish to be moved, and can communicate orders to those above by a signal line tied below to the bell, and going up to the ship, when some intelligent person must hold it in his hand, to feel the signals which the divers make by snatching it. To avoid the danger of mistakes, the signification of these signals should be painted round the inside of the bell. Thus one snatch signifies, make the bell rope fast to keep it stationary; two, means to descend; three, to ascend; four, to the north; five, to the south; six, to the east; seven, to the west. A board, with duplicates of all these, is to be kept near the person above, who will be very conveniently situated a-stride upon the yard-arm, so as to be directly over the bell, and will there have a view of all the ship's company, as well as the bell under water. The signal line should be a deep sea lead-line, such as seamen use to sound in deep water, with the usual marks to know the depths. These will show how far the bell is below the surface, and will be attended with the advantage of enabling the divers to denote the distance they wish to move, ascend or descend. Thus if they gently pull down two fathoms of the line, which the man above must give out, and take notice of the quantity, he will find they wish to descend two fathoms lower; the same of ascent, or progression sidewise, in any direction by the compass. To avoid confusion or delay, those of the ship's crew who are to haul the ropes for motion, ascent, and descent of the bell, should in all things be under the command of this man, and no other; but another should undertake the command of the people who manage the supply of air. He may be placed with great advantage in a boat, where, if he has another to assist him, he may be able to do the whole; for the barrels weigh very little in descending, and in ascending only as much as their bulk of water, which need not be above 20 gallons. Indeed as Mr Spalding says, one barrel of 30 gallons would be sufficient; and we think it would be more easily managed than two smaller ones.

Diving Bell.

The boat should have a piece of timber projecting several feet over her stem or side, in the manner of a ship's cat-head, or rather of an anchor boat, with sheaves in it at the end for conducting the rope for the air-barrel to a small roller with a winch, by which it is drawn up with very little labour.

The upper end of the leading line for conducting the air pipes down to the bell, should be led through a sheave in the timber, at a proper distance from the others, and should be held by the person above mentioned, who must take care to keep it always tights, giving it out when the bell descends, and taking it in when it is drawn up.

If the divers have any directions to give concerning the supply of air, they should do it by snatching this leading rope, and not the signal line, because the orders will then be sent to the proper person, viz. he who commands the boat. Thus his man winds up the barrel, till it comes above water, and fills with air, by the water running out at the open bung-hole in the bottom; then he lets it down again full of air, and the end of the flexible pipe is guided by the thimble running down the guide-line till it comes to the bell, where one of the divers takes it in, and opens the cock in the top of the bell to let out the air, till he sees the water rise in the bell to certain marks, by which he knows he has let out the exact quantity of air which the air barrel will replenish. As soon as the barrel has descended below the level of the surface of the water in the bell, he opens the cock in the end of the flexible pipe to admit the air from the barrel; but he must not do this before the barrel has become lowest, lest the bell air should take a contrary passage, and-issue through-the pipe from the bell into the barrel, and perhaps escape from its bottom into the sea. The cock at the end of the pipe is likewise very useful to admit the air gradually, lest by entering the bell, and suddenly displacing that quantity of water, which was just before gradually admitted when the hot air was let out, it should cause the bell to heave up. When the bell rests upon the ground or the deck of a ship at the bottom, it will be necessary to draw it up a little, to allow the air barrel to go lower and get the air into it; it will give a great facility to this, if the bell is made as above described, with pumps and a chamber above: then if this let out so much air from it as will make the bell, without its ballast or anchor weight, lighter than water, the divers, by letting out the rope of the balance weight, may suffer the bell to rise 3 or 4 feet without waiting to give orders to those above; the air being thus introduced from the barrel into the bell, they return the air to the chamber by the pumps; and if this does not cause it to descend, they haul it down again by the balance weight, then giving a snatch to the guide rope, the man in the boat feels it, and knows he is to haul up the air barrel to refill it with air.

To proceed with advantage, two divers should descend together, as they will then be able to manage with more confidence and expedition than if there was only one. The principal diver must be a man possessing great intrepidity and presence of mind, that he may proceed calmly to effect his purpose: He should be perfectly acquainted with every thing belonging to the bell, and the principles of hydraulics on which it acts, so as to have resources within himself for all that may occur; his companion should be completely under his direction to execute his orders, and should be an intelligent man, well acquainted with the management of the air barrel and the balance weight, which are to be his chief occupations, unless when his principal has other work for him to do, such as fastening up the ropes to the goods, and assisting in cutting away the deck of the wreck. For these purposes, the bell should be well furnished with tools, that nothing may be found wanting: a crow-bar, two axes, proper saws, and a large augur or centre bit are indispensible. One of the axes should be made exceedingly sharp, and kept for cutting away ropes from the ship's rigging, which are very dangerous to the bell in descending. These tools may be kept at the sides of the bell, hung in loops formed by leathern straps nailed upon the wood; there should likewise be provided a strong iron screw formed to penetrate and hold in wood, with an eye at the end. The divers should be dressed in thick flannel dresses, with high water boots to keep their feet dry. Each man may have a small rope made fast round his waist, and to the top of the bell, with sufficient length to allow him to work, but not to sink deep in the water if he falls. They should stand upon ropes stretched across the mouth of the bell, and have others fixed at a proper height to sit upon; also several fixed across the top of the bell, and hanging down a little to take hold of, in case of accident, as well as to obtain a hold for the purpose of lifting heavy goods, when they are clearing the wreck. If they intend to dive to the wreck of a ship, the diver should...
Diving Bell.

Previously make himself acquainted with every part of the ship's rigging and hull, also the manner in which the timbers are disposed, that he may know when he alights on any part of the ship's hull or upper works, where he is, the position in which she lies, also how to proceed to cut an entrance, if it is not practicable to enter at the hatchways. Having obtained information from persons best acquainted with the situation of the wreck, he should proceed to the place and moor his ship, so that the sun if it shines will be on that side of the ship where he intends to descend, otherwise her shadow on the bottom might fall on the wreck and throw him in the dark. Before he descends the first thing he should ascertain, by sounding, the most proper place for the descent, and there let down the balance weight of the bell to the bottom; then, with his assistant, he enters the bell, which we suppose is suspended from the yard arm, and standing upon the cross ropes, he orders it to be lowered gently into the water. When the air becomes much condensed by 10 or 15 feet descent, he must stop, and have as many barrels of air sent down as will fill up the bell again, and also as much as they can pump into the air vessel. The quantity of ballast is such that, in this state, it will not quite sink, and therefore requires the diver to haul it down by means of the balance-weight, which should be at least two and a half, or three hundred weight, so that it will cause the bell to sink, without being taken off the ground. By this means the divers govern the bell themselves, and the men in the ship above are directed, by the proper signal, to hold the bell rope just tight, so as to be ready if wanted; but they are to give it out as they feel it drawn by the descent of the bell, which is thus continued with perfect safety; for if the divers meet with any rope or spar of the ship or point of a rock, which puts them in danger of being swayed, they cease hauling the rope, to give the signal of stand fast to those above, and wait till they cut away or remove the obstruction; or if this cannot be done, they haul up their balance-weight off the ground, send orders to be drawn up a few feet, and then moved to the north, south, &c. many feet as they expect will bring them over the spot they desire. Here they again let fall their balance-weight, give the signal for let go the bell rope, and haul themselves gently down, stopping when they require more air, and making a signal for it to the man in the boat, by snatching the guide line of the air barrel. In this way they proceed till they come within sight of the bottom; and when they arrive there, the diver makes his observations on the position of the vessel; and if he wishes to move from his position, he orders to stand fast, hauls up the weight, and causes himself to be removed wherever he wishes, till having settled his plan of operation, and chosen a place to begin, he must, as the first thing, secure the means for descending to the same spot the next time. If he thinks he cannot accomplish his object at once, and if he must cut through the ship's deck or side, this is not to be expected; he therefore makes an augur hole in some part of the wood of the wreck, and screws the iron screw above mentioned fast into it, by turning it round with the crow bar; then into the eye of it he hooks the block of the balance-weight, or lashes the weight fast to it, so that it can be in no danger of removal. The divers then set earnestly to work to cut a hole either with their saws or other tools, as are best adapted to the purpose; but they should not continue down too long, because it is very injurious if the depth is great. When they are drawn up, or rather when they suffer the bell to rise, by giving away the rope of their balance-weight, the air in the Diving Bell will expand itself as the pressure diminishes, and bubble out from under the bottom of it; but if they find that the expansion of the air in the upper bell, by displacing more water, gives the bell too much power of ascent, they must let some of it out by the cock for that purpose, and thus regulate their ascent.

When the bell is hauled up out of the water, the divers quit it, getting into the boat, which is rowed beneath for that purpose, and other divers may descend immediately to continue the work; but if this cannot be done, and the ship is obliged to leave the station, the upper balance-weight block should be unhooked from the top of the bell, and made fast to a proper buoy or float, by which it can be found again when they return another time; then by applying the block to the bell, it may be taken direct to the bottom without any danger of obstructions, or any occasion for the cautions which were formerly requisite. By this system of managing the bell, it will be seen that all the manoeuvres can be executed quickly, which is a great object, as the operation of clearing an entrance to a ship is in itself so tedious, where only two men can work at once, as to admit no loss of time in the minor operations of descent, &c. The bell, when in the water, will weigh scarcely any thing, and therefore one or two men will be able to manage the bell rope without any purchase or windlass, and will, by simply hauling, have it more readily in command; but as its weight, when it is to be taken out of the water, will be very considerable, they must then apply a strong purchase. To do this with convenience, let the bell rope have a three sheaved block attached to the end of it, a similar block to be lashed to the bell, then revolve as much rope through these blocks as will allow them to be at 15 or 20 feet asunder, and make the fall of this tackle fast to the lower block, so that its end cannot get loose. When the bell is below water, this tackle will be useless, and only suspend the bell, in the same manner as the plain rope would do if it was continued to the bell. It is only used to hoist the bell above water: thus the bell rope is taken up as the bell rises, until it comes near the surface; the upper block of the tackle will then have come up to the yard arm; and it is obvious that it cannot be raised any higher by the bell rope; therefore make the fall of it fast on deck, to afford a suspension for the upper block of the tackle: A few men, by taking hold of the fall, will now have a sufficient purchase to raise the bell up from the water. Of course, in descending, this fall must be given out till its end, which is fast to the lower block, comes tight, and the bell is settled down in the water, before the bell rope is released; by this means the men will never lose time by using the purchase, except when the weight to be raised requires it.

When the divers have so cleared the wreck that they expect to have goods to send up, the tackles for that purpose should be provided. They may very conveniently be suspended from the fore yard-arm of the ship, whilst the bell hangs at the main-yard. There should be a separate crew for this tackle, who take their orders from a person who receives signals from the bell, by means of a guide-line, similar to that of the air barrels. The hook or tongs at the end of the tackle should be connected with this line by a thimble, and then being let down, it will slide to the man in the bell. There should be two or three tackles, that no time may be lost in waiting; and if they are made with blocks in the lower part, as above described, for the bell rope, they will be very convenient for the same reason, viz.
that many of the goods weigh very little in the water, though when they are taken out they require a purchase; for this reason, the boat should attend as soon as they appear at the surface of the water, and make them fast by another sling, because it cannot be expected that the divers in their hurry will be able to sling the goods quite so fast to the rope, as may be sufficient to raise them out of the water, though it has brought them from the bottom.

An apparatus more convenient than the preceding when the bell is to be used in a river or still water, is shewn in Figs. 7, and 8. of Plate CCXXII. The bell is here suspended between two boats of 15 or 20 tons burden each, or they may be such barges as are used on the Thames for transporting coals. These two are well secured together by cross beams, DD, which preserve them at the same distance, and likewise form the base of a wooden frame DEF, lying across the barges, supporting a beam E, from the middle of which hangs a strong block M for the rope, by which the bell H is suspended; the other end of the rope goes round a windlass, a, Fig. 7, with a ratchet wheel and click, to raise and lower the bell H as occasion requires. b, d, Fig. 8, are smaller blocks, for the ropes to draw up the air barrels; e, f, are rollers, turned by winches, which come close together, so that one man can turn them both at once; and when one rope descends, the other ascends, so as to give a constant supply of air to the divers under the bell H. When the divers wish to come up, they give a signal to that effect, and the windlass is turned by men until the bottom of the bell is brought above water. A small boat or raft is rowed under the bell to take the divers out: the same method is to be used to get them in; and this will be done without wetting them, or any other inconvenience. The signals may be given by a line, in the same manner as before described; but as the depth for which such a bell is intended is but small, an air-barrel may be found sufficient; and the air-chamber, or small bell above, will not be necessary. In some cases, the air may be more conveniently supplied by an air-pump and leather pipe, on Mr. Smeaton’s plan, which we shall describe.

An apparatus of this kind would be extremely useful in any large river such as the Thames, where barges are constantly sunk, meurings lost, &c. It would give the means of removing sunken rocks, which, though too deep to be blasted by the usual methods, may be very dangerous to ships, such as the rock in the Thames at Blackwall, upon which several valuable East India ships have at different periods been wrecked. To proceed in such a business, the divers should descend upon the rock, and with a jumper bore a deep hole in the rock in that place where the powder will be likely to have the best effect; in this hole, a tin canister, or glass bottle, containing a proper quantity of gunpowder sealed up and well secured from the water, is to be inserted, and the remainder of the hole filled up in the usual way of miners, with pounded ashes, brick-dust, or sand. To fire off this powder under water, is the only remaining difficulty: This may be done, by having a large tin canister communicating with the former, by a very small tube filled with powder, for priming and leading up to the pan of a common gun lock, contained within the space of the upper canister, and thus defended from the water: A wire from the trigger of the lock is to be conducted through the side of the canister, with proper fittings of leather to make it water tight; and there must also be a wire handle coming through to cock the lock ready for discharging: its fitting should be secured in the same manner. Then tying the end of a small line to the trigger-wire, the diver coils several yards of it upon the rock, cocks the lock, and orders the bell to be drawn up, taking the end of the line with him, but being exceedingly cautious not to pull it till he is above water; and it is to avoid this that the coil of line is laid on the bottom. When all is ready, he draws up the slack of the line, and fires off the powder by snatching the line.

We have heard of gun-powder being fired under water by means of a metal wire leading down to it, and transmitting a strong shock of electricity through the powder to ignite it by the spark. Part of the Aberdovey wreck was broken up by gunpowder to obtain an entrance into her, before the method of cutting her planks and timbers was employed.

The diving-bell appears, at first sight, to be capable of very extensive use to engineers, in constructing the foundations of bridges, piers, sluices, and other works of hydraulic architecture. It would obviate the necessity of coffer-dams to inclose the area of the foundation, and of the engines for drawing out the water, preparations which are generally the occasion of greater labour and expense than the masonry or other work to be performed. Or admitting that the diving apparatus in its present state is not capable of being carried to such a degree of perfection as to construct the whole of new works, there is no doubt it would be very practicable and satisfactory to a surveyor to have the means of examining the state of his work under water, or making trifling repairs, which, from the great difficulty at present of gaining access to the parts, are neglected and deferred until they become of serious extent.

Notwithstanding all these apparent advantages, only two instances have come to our knowledge of the diving bell being efficiently employed by engineers; both were under the management of the late ingenious Mr. Smeaton. His first attempt was to repair the foundations of some of the piers of the bridge over the Tyne, at Hexham, in Northumberland, where the force of the current had excavated the gravel bed of the river, between some of the timber floors on which the piers had been built by the engineer method. He succeeded, by the assistance of his diving-bell, in filling up the cavities beneath the foundations with large rough stones, which were not disturbed by the current, although the evil gained upon the remaining parts of the foundations too fast to be preserved by any method; and on the occasion of a violent flood in the year 1782, the whole structure was carried away in the course of a few minutes after it appeared to be in danger. This diving bell was a square chest of wood, three feet six inches, by two feet at the base, and four feet high; and was supplied with air by means of a pump.

In 1788, Mr Smeaton caused a second diving chest to be made for the purpose of getting up a quantity of large stones, which some years before had been thrown into the sea at Ramsgate harbour, to secure the foundations of the outer pier head. It was in contemplation to build an advanced pier beyond this, and it therefore became necessary to get up these stones; but as many of them were above a ton in weight, the usual method of lugging was not found applicable; whereas by this machine one hundred tons were got up in the course of two months.

Instead of the usual form of bell or of a conical tube of wood, sunk by weights (externally applied) cast iron...
Diving Bell.

This bell was a square chest of cast iron, which weighing
50 cwt. was heavy enough to sink itself, and being 44 feet in height, 41 feet in length, and 3 feet wide, afforded room sufficient for two men at a time to work under it. But it was peculiar to this machine that the men were furnished with a constant influx of fresh air, without any attention on their part, that necessary article being amply supplied by a forcing air-pump in a boat upon the water's surface. Fig. 2. Plate CXXXII. is a plan, and Fig. 3, a section of this chest. The bottom part, AB, is made very thick, to give it sufficient weight, and in the crown are eight round holes, a, a, Fig. 2, each being provided with a lens or glass of four inches diameter, fitted into a brass cell, and then screwed into the cast iron. In the centre is a hole b to receive a brass screw at the end of the leather pipe, which introduces the air. This hole, on the underside, has a leather valve stretched over it, to prevent the return of the air; and the hole has a kind of grating of iron across it, to support the valve against the pressure when it is shut. The valve is nothing more than a square piece of leather stretched over the hole, and fixed to the iron cell by a screw at each corner, not so tight but that it can open to admit the air, though it is always kept in its place; d d are two strong eyes to receive the chains which suspend the bell, and there are similar eyes within the crown to suspend an iron link M, to which chains may be attached. The whole is cast in one piece; e e are two seats for the divers to sit upon as they descend, but these turn upon hinges when they descend and go to work.

The pier, which was afterwards built upon the foundation cleared by this machine, was founded by caissons; but not being done very substantially, or with large stones, the work has in the course of years become so bad, as to require renewal in some places, and in others to be defended by an apron or outside wall of very solid masonry, which has been all laid by the diving bell. This operation is still going on every summer, and the apparatus employed is shewn in elevation by Fig. 1. and a plan at Fig. 5, where AA represents the same cast iron bell, attached by two chains to the three-sheaved block a; another block, b, with three sheaves, is supported between two long timbers DE. These are united to form one frame, as shewn in Fig. 5; and to strengthen them, king posts F, and riders GG, are erected upon them, and very strongly tied to the iron straps, and wooden knees. These beams traverse upon a centre pin d, which is fixed into a very heavy stone; and they are likewise supported by small wheels which run upon a rail-road H, which is curved to a segment of a circle, as shewn in Fig. 5. The extremity E of frame has a heavy stone attached to it, to balance the weight of the bell appended from the opposite end. The fall of the tackle is conducted through a block x, to a capstan, by which it is taken up or let down. This machine is placed upon the top of the pier wall IK, Fig. 1, at the foot of which the stones dotted at LM are to be laid by the divers. The different motions are thus given to the bell: to bring it nearer or farther from the wall, the block b is moved in the beams, and for this purpose it is made to slide freely between them; to haul it in, a pair of blocks e, f, are used, and it is drawn out by a rope passing through a block at D, and then to the pair of blocks g, h, Fig. 5; to move it sidewise, two pair of tackles are applied at i, k and l, m; R is the leather pipe conducted from the bell to the forcing pump N, which is fixed on board the boat, Fig. 4, and is worked by the lever handle n; w is a rope extended from the bell to the boat, and being shorter than the pipe, it prevents it from being broken or stretched by the wind or tide carrying the boat away; and it is also secured to the pier by the rope p. The man at the pump N is directed to force down so much air to the bell as will cause the air to flow out beneath the lower edge of the bell, and rise in bubbles to the surface; and as long as this continues, he knows that the divers are well supplied with air. As the depth in which this machine is used is very small, the signals are not made by a line, but by the divers striking with a hammer upon the inside of the cast iron of the bell: This produces a peculiar sound, which can be heard very plainly above, and is not liable to be mistaken for any other noise: the number of blows denotes what they wish, according to the following table, which is painted withinside the bell, and the people above have a duplicate of it.

1. More air. 5. To eastward.
2. Stand fast. 6. To westward.
3. Heave up. 7. From the wall.
4. Lower down.

The manner of proceeding is this: The stones are all prepared, and jointed together with dovetails, before they begin to lay them; and the first thing to be done is, to make the foundation perfectly level and true. The loose sand, &c. is removed, by dredging from above in the usual manner; and then the bell, with two men in it, is let down to the bottom, which, at Ramsgate, is a hard chalk rock; when it stands thereon, it lays the chalk dry to the level of the bottom edge of the bell; but if the surface is uneven, the bell cannot descend so low but that it will leave 6 or 8 inches of water on the bottom. The surface of this water is the level they work to, and by cutting away every eminence which rises above the water, they soon obtain a perfect level surface. They work with a small pick, made something like a narrow adze, for this purpose; and the work proceeds rapidly, for the chalk is not very hard. When they have accumulated as much rubbish as becomes inconvenient, they give three knocks on the bell to order the people to draw it up, till they, standing on the bottom, find themselves knee deep; then two knocks to stand fast. They now take in a shallow basket which has been previously let down from above, and fill the rubbish into it; then snatch it to order it to be drawn up, and strike four times on the bell that they may be lowered down to proceed with their work. Having in this manner heaved away the surface till the water standing equally all over it, shews it to be a perfect level plane, they give orders to be removed to a new situation, yet at such a small distance that part of the surface they have been levelled, is still beneath the bell, in order that both may be brought to one plane. Thus continuing the work, they get all the rock prepared for the stone work, without any other level than the water. To hoist the stones which are to be laid, they use a crane, of which the reader will find a description and figure under our article Crane. It moves on wheels, and can therefore be wheeled upon the pier to the required spot, close to the diving machine. The first stone is taken up by it out of the boat, the hooks of the crane being put in the ring of a lewis, which is an iron wedge, so fitted into a hole in the stone, that it will not draw out by the weight of the stone, though the mason can relieve it in a moment. The stone is turned round into the position in which it is to be laid, and lowered to the bottom as close as is convenient to the
DIVISIBILITY OF MATTER. See Physics.

DIVORCE, is a judicial separation between man and wife, more or less complete, variously affecting the conditions of the marriage-contract, and allowed for different reasons, and to each, or only one of the spouses, according to the respective municipal institutions of different countries.

In ancient Greece and Rome, and perhaps in all pagan countries, the marriage bond was entirely broken, leaving the parties at liberty to form other matrimonial alliances, as if no previous marriage had ever existed. At Athens, and in the later period of the Roman republic, the right of divorce was equally exercised by both sexes, although, in the earlier ages of Rome, it belonged exclusively to the men. In both countries, too, it was permitted on a variety of grounds, such as adultery on the part of the wife, imposing supposititious children on her husband, counterfeiting his private keys, &c. desertion on the part of the husband, unnatural severity towards his wife; and, on either part, sterility, old age, or other infirmities; till at last, the most frivolous reasons, and even mutual consent, were regarded as sufficiently competent grounds for thus totally dissolving the matrimonial connection. The effects upon the conditions of the contract, in other respects, were various, according to circumstances. The most important were, that, where the divorce had taken place, in consequence of the wife's infidelity, she forfeited her dowry; when without any fault on her part, she reclaimed it, and was also allowed to retain the presents which had been made her by her husband.

The introduction of Christianity created a great change in most countries of Europe, on this particular of their municipal institutions. Marriage, which, from its intimate connection, not only with the happiness of the married parties themselves, and of their offspring, but also with the general welfare of the community, is, even in rude and early stages of society, frequently found blended with the ceremonies and sanctions of religion, came now to be regarded as much in a spiritual as in a civil light. The Romanists exalted it to the rank of a sacrament; and, reasoning from the text of scripture, which says, "whom God hath joined together let no man put asunder," their canonists maintained, that divorce, in the sense of the heathen world, was altogether impious and impossible.

According to the Roman institutions, therefore, there is no such thing as divorce, properly so called. They admit not of a total dissolution of the nuptial bond for any cause whatever; so that if a party be once truly joined, neither the death of one of the spouses can put the other in a condition to form a new alliance. At the same time, they admit certain causes, such as severe treatment of the wife, adultery by either of
the spouses, intolerable temper, as sufficient to authorize a partial separation, or a *mensa et thoro*, by which the cannabial society is broken up, while the marriage itself continues to subsist. It must also be observed, that if certain impediments existed *at the time* the marriage was entered into, and not afterwards supervening, such as nonage, corporal imbecility, and many others, the marriage is, by the Roman institutions, capable of being totally annulled. But as in the former case there is properly no divorce, the marriage still subsisting to many important effects; so neither in this can the term, at least in its ancient signification, be applied, there being strictly no dissolution of a marriage, but rather a declaration that, *ab initio*, there was none, by reason of the impediments that had all along existed in bar of it.

As most of the countries of Europe fell under the influence of the Roman church, this came, of course, to be the prevailing notion regarding divorce; and, even when the Protestant countries had asserted their spiritual independence, views of sound policy induced many of them to entertain the same ideas regarding the indissolubility of the nuptial yoke, which their religious instructors had formerly imposed.

In England, in particular, the law of divorce continues to this day, precisely as regulated by the Roman canonists. No divorce, properly so called, can be obtained, for any reason whatever. A special enactment by the whole legislature is necessary for each particular case. Nor have even the legislature been hitherto induced to interfere, but in the case of the highest injury suffered by one of the spouses—infidelity to the marriage bed, which must have previously been the subject of a regular suit and conviction in the competent court of law. In case of *divorce a mensa et thoro*, (for the law of England applies the term to that partial separation of the married pair,) alimony, or the means of subsistence, is allowed to the wife out of the husband's estate; and it is adjusted by the judge according to the circumstances of the case and of the parties. If the divorce, however, has been obtained by the husband against the wife, on the ground of adultery, and she continues to live with her paramour, the law denies her any support out of her husband's means.

By the law of Scotland, besides a separation *a mensa et thoro* merely, divorce properly so called is authorised. The grounds upon which it may be sought are specified to two—adultery by either of the spouses, and desertion for the period of at least four years. These are the reasons which the Scottish reformers, disdaining to be trammelled by the Roman institutions, founded warranted by Scripture, *Matth. v. 32; 1 Cor. vii. 5.* In this action the commissioners of Edinburgh are the only competent judges in the first instance; and before they can proceed to consider the grounds of the action, the pursuer must make oath that it is in no respect collusive. The marriage bond is entirely broken by the judicial sentence, there being no limitation upon the parties from forming any new connection, except that by express statute, 1600 c. 20, if the divorce has been obtained on the head of adultery, the offending parties are prohibited from intermarrying; a wise regulation, since otherwise the crime might often be committed in the very view of accomplishing such a marriage. In the case of desertion, the absence must be wilful and malicious, and the party deserting must first be ordered by the judge ordinary to adhere. On default, denunciation, as it is called, must follow, and afterwards excommunication by the church. The commissioners may then proceed to give forth their sentence of divorce. If the wife has been the offender, either in the case of infidelity or desertion, she forfeits her *tocher* (or dowry,) to the injured husband, together with all the provisions which would have accrued to her upon her husband's decease, whether these have been fixed by contract between the parties at entering into the marriage, or have been left to the general disposition of law. If, on the other hand, it is by the husband's desertion that the divorce has been occasioned, he both restores the tocher, and makes good the provisions in favour of the wife, to which he is bound either voluntarily or by law. But it has been decided, that where the divorce proceeded on the ground of the husband's adultery, he is not liable to restore the dowry, but only to make good the wife's legal or conventional provisions.

Of late, our neighbours in England have manifested some disposition to avail themselves of the facilities afforded by the Scottish institutions for obtaining divorces; and certain individuals, passing the border, and obtaining a domicile in Scotland, have contrived accordingly to accomplish their purpose—an indication not inconsiderable of the increasing dissoluteness of manners among that people. To what extent the courts of England may be disposed to countenance the proceeding is not yet ascertained. That it is, however, a matter of high concernment to the national policy, is sufficiently obvious; while, at the same time, it furnishes a very curious and difficult subject of speculation as connected with that courtesy which the judicial establishments of one country ought, as much as possible, to practise towards those of another. It forms, however, only one instance of the general doctrine of this courtesy of nations, or, as it is termed among professional men, the *comitas gentium*. We therefore avoid entering upon it at present, as a fit opportunity will occur under the article *Law*, for discussing together the whole principles of this nice and delicate subject. *(i. n.)*

**DIURIS**, a genus of plants of the class Gynandria, and order Diandria. See *Botany*, p. 344.

**DIXAN**, a town of Abyssinia, is situated on the summit of a conical hill, and is encircled with a deep valley like a trench. The hill commands an extensive prospect of the mountains of Tigré, and the country around, which consists chiefly of rocky mountains, many of which have villages like Dixan. The road to the town is a spiral ascent, which has a fine effect. The houses are flat roofed, and have no windows. Instead of chimneys, they have two very narrow earthenware pots, rising out of the roof. The only public building here is the chapel, which consists of mud walls, and a conical thatched roof. When Mr. Salt entered the door of the enclosure, the boys who conducted him kissed the door posts. The inner building was shut, and the surrounding circle, which was strewed with rushes, had its walls covered with various strange figures in glaring colours, among which were St. George and St. Haimonout on horseback, with spears. The inhabitants bring their water from a valley about a mile from the town. The best articles for barter here, are tobacco, black pepper, looking-glasses, snuff, spirits, and large green beads. White cloths are preferred by the people to those of any other colour.

The town is inhabited by Moors and Christians. Every man has from one to ten wives, according to his wealth. Boys marry at 14 years of age, and girls at 10, 11, and 12; and the children are circumcised by the women when they are eight days old. All the
DIXMUDE, DIXMUDE, DIXMUD, DIXSMUTZ, a town of France, in the department of the Lys, is situated in a fertile plain on the river Yperle. It had formerly four convents, and is celebrated for the excellent quality of its butter and cheese, which is obtained principally from the territory of Furnes. It was once a strong place. A fair is held here on the third Sunday of July, which lasts eight days, and at which are sold cattle and various articles of merchandise. Population 2521. Distance from Dunkirk 24 miles east, and from Furnes and Nieuport nine miles north. (J)

DIZIER, St. Sacre, Desiderii, Fanum, is a town of France, in the department of the Upper Marne. It is situated on the right bank of the Marne, at the place where this river becomes navigable. The fortifications of this place have been greatly neglected. The road between Vitry and St. Dizier is reckoned the finest in Europe. Between this town and Joinville, there was discovered, in 1772, the ruins of a Roman station about 2900 feet long, and 1800 feet wide. There are several iron mines and forges in the neighbourhood, and the principal manufactures are cast iron, linen cloth, hosiery, hats, and leather. It carries on also a very considerable trade in wood, particularly in that which is used in the construction of ships; the depot is at St. Dizier, where it is embarked on the Marne, and conducted to Paris. A great number of boats are built here, and a considerable trade is carried on in corn and iron. Population 5834. (m)

DNIETER, NIEPER, DAXAPIS, the Borysthenes of the ancients, is one of the largest rivers in Europe, and the chief river of all the provinces adjacent to the Euxine. It rises in the government of Smolensk, near the same place as the Volga and the Southern Dvina; and after running southwards through Lithuania, the country of the Zaparog Cossacks, and that of the Na-gay Tatars, it discharges itself into the Euxine or Black Sea, at Kiburn, near Oezakof. The Dnieper is navigable from Smolensk, if not from Dorogobush; but its navigation is badly obstructed by numerous flats or moving sands, common to all the rivers in the north of Russia, and by numerous cataracts. From Kiof, downstream, the navigation is greatly recommended by the flats in the middle of summer. Channels of considerable depth exist near the shore on both sides, but these are constantly shifting during the floods; and the only method of remedying this evil is to have pilots stationed at particular places to sound the river, and direct the vessels into the right channels. This has already been done with great effect in the river Svir.

The cataracts of the Dnieper, formed by huge blocks of granite projecting into the river, are a still more formidable obstacle to its navigation, as the banks can get over them only at high water during the spring. During the government of Potemkin, an attempt was made to clear the cataracts, but the work was stopped by the war in 1767. Since the commencement of the present century, the attention of the emperor has been strongly directed to this subject. The Board of Inland Navigation has begun to deepen a channel between the cataracts, by means of temporary dikes through which the banks may pass both up and down the river in the very middle of summer. This plan, however, is far from being quite inapplicable to the great Neussandez cataract, they began to dig through a rocky shore at a circuitous canal round it, provided with sluices. The clearing of other three cataracts were begun, and eight remained to be executed. These works were going on slowly in 1805 when Mr. R. Corner visited that country; and he informs us, that a float of timber, which arrived while he was at Odessa, had spent two years in coming down, from the impediments of the cataracts. Below the cataracts, the Dnieper resembles the Volga, and is intersected with many islands and flats. The current, which is not strong, admits of the use of oars for vessels going up, and of sails when there is very little wind. The marshy nature of the shores has rendered it necessary, in some districts, to establish towing paths, which will be of the greatest service in accelerating the return of barks with salt, silk, cotton, and the other products of the Levant, which are absolutely necessary for the inland manufactories. The lemon or estuary of the Dnieper, is extremely hostile to the export trade. It flows slowly into the Euxine, through several branches, and forms numerous sand banks; so that in summer, when there is scarcely six feet of water, merchant vessels are obliged to land 35 versets beyond its mouth, at the Gubolitaya pristan, or deep wharf. Even this place is very unfit for the purpose, as the road is sometimes un navigable from November to May; and when the dock-yard was at Cherson, it became necessary to use canoes for transporting the men of war over the sand flats in the estuary. From these causes, Nicolae, situated on the Bog, and the Ingul, was chosen for the seat of the admiralty; but being found inconvenient for trade, on account of its distance from the Dnieper, the port of Odessa was constructed on the bay of Had-giby, which was particularly eligible on account of its vicinity to Poland, Podolia, and Volhynia. Maga- zines and storehouses have been erected for the goods brought down the Dnieper, and also along the banks of the Dniester, for the products of Galicia and Podolia.

About 300 vessels descend the Dnieper to Nicoloaf and Cherson, and vast floats of timber are brought down for the admiralty. About 60 boats laden with salt ascend the Dnieper from Kremenchuk to Smoles-insk, and also several of its branches, to the wharfs of Novgorod, Severskoy, Pinsk, and Borovitz. This salt is conveyed by means of oxen from the Crimea to Kremenchuk; but when the cataracts are cleared, the land carriage will be diminished to 1300 versets from a circuitous canal, from the Crimea to the wharf of Berezasskoy on the Dnieper, and the salt may be carried by water from the salt pits of Kiburn.

Many of the streams which fall into the Dnieper are navigable, or capable of being made so, excepting in seasons when the parent river is itself unfit for navigation. The principal of these are the Drusa, which is small and unnavigable, joining the Dnieper at Rogatchef; the Beresina, a pretty considerable river, by which masts are floated down to Borisof, and even to the wharf of Pedoezerskoy; the Sosha, which is navigable in July for 500 versets, and supplies Kiof with timber; the Pripit, which is the chief branch of the Dnieper, separating Lithuania from Volhynia, and carrying down great
quantities of timber; the Teterova, capable of being made navigable down to Ortomis; the Desna, which runs through the most fertile and best wooded districts, and is navigated for 800 vers from Tchernogof, Novogorod, and Severskoy to Bransk, by from one to 300 barks annually, while a greater number returns to it with salt; the Soluta, which is navigable from Luben; the Peisof, which flows through a steppe, and is navigable in spring; the Torfska, which could be made navigable to Akia in the Ukraine; the Samara, which will soon be employed in conveying to the Dnieper the newly discovered coal near Paflograd; the Inguletz, a considerable river of the Steppé; and the Bog, or Bugg, which falls into the estuary of the Dnieper, about 30 vers above Oczakof, and is one of the chief rivers in the country, admitting ships of war 150 vers from its mouth. See Tooke's View of the Russian Empire; and particularly Clarke's Travels, vol. i. 2d edition, p. 768. (x)

DNIESTER or NESTER, a river which separates the dominions of Russia from those of the Ottoman empire. It passes by Halics, Choczim, Saroka, Ras-cow, Egerlik, Bender, &c. and discharges itself into the Black Sea at Akerman. It is a river of very considerable magnitude, and is navigable for vessels of a moderate size. It is in general deep, and even in seasons of drought may be navigated by vessels not drawing above two feet of water. There are many shallows, however, in the upper part of the river, which in summer have not above 2½ feet of water. The cataract over a granite ridge at Yampole, which formerly obstructed the river, is now cleared away, and the establishment of towing paths has been in contemplation by the Russian government since the peace of 1791, and is probably already completed.

The Dniester forms, at its embouchure, a shallow leman or gulf, which will not admit vessels that draw more than five feet of water. It is three vers long, and about five broad, and joins the sea by two different branches. A Russian flotilla, however, during the last war, went up to the very walls of Bender. A considerable trade is carried on from Odipiopolis to Akerman. On the upper part of the Dniester are four principal wharfs, viz. Stria and Salezic in Austria; and Svanetz and Dubozar in Podolia. The Lemen of the Dniester abounds in fish, particularly in sterlet and sturgeon.

The tributary streams are the Kuzorgan, a torrent which is dry in summer, and falls into a fresh water lake of the same name joining the Dniester; the Botua, which rises in Bessarabia, and is a small and marshy stream; the Komorofka, a torrent of the Steppé; the Yashlik, Chemaya, and Tamanishik, which are mere torrents, and the Yarleka, which has a great deal of water, and a stony bottom, and runs so near the Bog, that it was once proposed to unite the last with the Dniester. The Dniester separates into two branches, one of which keeps its name, and the other is called Stric. The first branch is navigable as far as Sambor, and the second to Stric. The Peloças, a small stream, runs into the Dniester at Samorod, by means of which, the Austrians intended to join this river with the Vilia. See Clarke's Travels, 2d edit. vol. i. p. 779. (x)

DOBBERAN, a town of Germany, in the Duchy of Mecklenburg, and kingdom of Saxony, is situated about two miles south of the Baltic. It was formerly celebrated for its monastery, which was founded in 1170; but it is now famous as a watering-place, which is much frequented by the first families in the north of Germany. The baths, which possess every kind of accommodation, are delightfully situated in a wood upon the Baltic, about two miles from the town. There is a warm bath, and nine cold baths, besides several bathing machines, and accommodation for invalids who are unable to walk or ride to the shore. There are two excellent hotels in the town, and a number of elegant and commodious lodging houses. A full account of this watering place, and of the various amusements which are provided for the company, will be found in Reeper's Geschichte und Anekdoten von Dobberan, nebst Beschreibung der dortigen Seebad.—Anzahlen. New-Strietiz, 1801, 8vo. See also Reichard’s Guides des Voyageurs en Europe, tom. ii. 4mo edit. p. 202. (j)

DOCKS. See NBOUR.

DODARTIA, a genus of plants of the class Dildynia, and order Angiosperma. See Botany, p. 254.

DODDRIDGE, Philip, an eminent tutor and divine among the Protestant dissenters, was descended of an ancient and respectable family, which appears to have been originally settled in Devonshire. His father, Daniel Doddridge, traded as an oilman in the city of London, and was heir-at-law to a considerable estate of about £2000 a year, but was deterred from prosecuting for its recovery by an apprehension of the hazard and expense. His mother was the only child of the Rev. John Bauman of Prague, whose adherence to the Protestant religion induced him, in 1625, to leave his native country, and a considerable estate; and who, after his arrival in England, was elected master of the free-school at Kingston-upon-Thames. Dr Doddridge was born at London on the 26th day of June 1702, and was the last of twenty children, who all died young, except himself and one sister. At his birth, he was so utterly destitute of every sign of life, that he was thrown aside as dead; but one of the attendants having observed some appearance of breathing, his existence was, with great care, providentially preserved for the benefit of mankind. From his infancy, however, he possessed an infirm constitution and consumptive habit, which rendered both himself and his friends apprehensive that his life would be short. He was trained up by his parents in the early knowledge of religion; and before he could read, was instructed by his mother in the history of the Old and New Testament, by the aid of some painted Dutch tiles in the chimney, while she accompanied her explanations with such suitable reflections, as made a lasting impression upon his mind. At ten years of age he was sent to the school at Kingston-upon-Thames, which had been taught by his grandfather Bauman, where he continued till the year 1715, equally distinguished by his pious disposition, and his application to learning. At this period, he was left an orphan by the death of his father; and at the same time, by the misconduct of the person who had been entrusted with the management of his pecuniary affairs, he lost the whole of his private fortune. But having been removed, at the time of his father's death, to a private school at St Albans, he happily formed an acquaintance with Dr Samuel Clark, describing minister of the place, who, continuing, through life, to treat him with all the kindness of a parent, and by whose generous assistance he was enabled to proceed with his future studies. During his residence at St Albans he began to keep a diary of his life, which affords ample testimony of the diligence with which he improved his time, and of his anxiety to be daily advancing in knowledge, piety, and usefulness. In the year 1718, he withdrew from school.
to the house of his sister, who had married Mr. John Nettleton, a dissenting minister at Ongar in Essex; and there employed himself in seriously deliberating upon his future profession. He was strongly inclined to the office of the ministry; but the narrowness of his circumstances presented little prospect of his wishes being accomplished. The Duchess of Bedford, who entertained a regard for his family, offered to support the expenses of his education at either of the universities, and afterwards to provide for him in the church of England; but, as he could not conscientiously comply with the terms of conformity, he declined the proposal with the utmost gratitude and respect. Others among his friends advised him to pursue the study of the law, and every favourable offers were made to him by a gentleman of that profession; but while he was deliberating upon the subject with devout applications for divine direction, he received a letter from Dr. Clerk, proposing to take him under his care if he chose the ministry upon Christian principles. Thankfully embracing this offer, he returned to the house of his friend at St. Albans, where he was furnished with books and directions in his studies; and, in October 1719, was placed under the tuition of the Rev. John Jennings, in the Academy at Kibworth, in Leicestershire. Under the direction of this gentleman, he prosecuted his studies with uncommon diligence; and besides perusing with close attention the most valuable theological works, he greatly increased his acquaintance with classical literature, especially with the Greek writers, upon many of which he wrote observations to a considerable extent. Nor was he, at this time, attentive merely to the acquisition of useful and ornamental knowledge; but was equally ardent in the cultivation of personal religion, as appears from the rules which he drew up for the regulation of his temper and conduct. In 1722, having been previously examined by a committee of ministers, and having received an ample testimonial of his qualifications, he preached his first sermon at Hinckley, whither Mr. Jennings had removed. After continuing to pursue his studies another year, he received, much about the same time, an invitation from a small dissenting congregation at Kibworth, and an application from the city of Coventry to be assistant to Mr. Warren; but preferred the former situation, partly on account of his youth, and also of the opportunity which the retirement of an obscure village afforded for the farther acquisition of knowledge. It was during his residence at this place, from June 1723 to October 1725, that he more especially excelled as a preacher. He was remarkably careful in his preparations for the pulpit, drawing up both his sermons and expositions with great exactness of method, and expressing his sentiments in language at once correct and elegant, and yet plain and easily understood. He was also regularly employed in the serious perusal of writers on practical divinity; and among these his favourite authors were Tillotson, Baxter, and Howe. Nor amidst his more serious pursuits did he discontinue his attention to polite literature; but frequently read the more elegant writers of the French nation. He particularly admired Fenelon and Racine; and among their sermon-writers, whom, however, he did not generally esteem, he gave the preference to Superville and Saurin. While thus solicitous to enrich his mind with various acquirements, he was duly attentive to the private duties of his station; and equally careful to adapt himself in conversation to the capacities of the humble people under his care. From the time that he entered upon the ministerial office, he received several invitations to more numerous congregations than his first settlement, particularly to a large society of dissenters in London, and to two similar associations in Nottingham; but after mature deliberation, he adhered to his plan of prosecuting his own improvement in a more retired residence. In 1729, he was chosen assistant to Mr. Some at Market-Harborough, where he had chiefly resided during the four preceding years; but he still continued to preach alternately to his people at Kibworth. Mr. Jennings considering Mr. Doddridge as the most likely of all his pupils to carry on and complete the plan which he had formed for conducting a theological academy, had earnestly advised him, but without mentioning his motive, to keep in view the improvement of the course of lectures which he had attended. Agreeably to this advice, he had carefully reviewed the compendium which he had made of these lectures; and having had occasion to draw up, at the request of a friend, a plan of conducting the studies of young men intended for the ministry, his own qualifications for the office of a tutor became more generally known. His plan had been shown to Dr. Watts, who not only expressed his approbation, but concurred with many others in the opinion, that the person who had devised was the best qualified to execute the scheme; and the matter having been proposed by Mr. Some to a meeting of dissenting ministers at Lutterworth, Mr. Doddridge was unanimously solicited to undertake the office of a theological tutor. After much hesitation, and with the utmost diffidence, he at length gave his consent; and having availed himself of all the information which he could derive from the best treatises on the education of youth, and the communications of his numerous friends, he opened his academy at Market-Harborough in the summer of 1729; but had scarcely continued a few months in this employment, when he was invited to undertake the pastoral charge of a congregation at Northampton. To this place he removed at the close of the same year; and for the space of twenty-one years, continued faithfully to discharge the duties of his pastoral office, and to conduct the business of his theological academy. At first, after his removal to Northampton, the number of students under his care was very limited; but gradually increased every year, so as to render it necessary for him to employ a stated assistant to superintend the junior pupils. During the 22 years that he exercised the office of a tutor, about 200 young men were placed under his care; and of that number 120 afterwards entered upon the ministry. In 1730, he married Mrs. Mercy Marias, a native of Worcester, who possessed every qualification that could minister to his happiness, and to whom he uniformly testified the greatest tenderness and affection. From his settlement at Northampton in 1729, to the commencement of his last illness in 1750, he produced a succession of the most valuable works, of which an account will afterwards be given, and which have proved instrumental of the highest benefit to the best interests of the human race. By these fruits of his pen, his name became more extensively famous. And in 1736, the colleges of Aberdeen united in conferring upon him the title of Doctor in Divinity. Upon this occasion his pupils testified their respect by offering their congratulations in a body; but he said to them in reply, "that their learning, piety, and zeal, would be more to his honour, and give him a thousand times more pleasure, than his degree, or any other token of
public esteem." The incessant application, which these various labours required, often excited the apprehensions of his friends; and at length impaired his naturally delicate frame to such a degree, that it was unable to stand the attack of disease. In December 1750, he went to St Albans to preach the funeral sermon of his venerable benefactor Dr Clerk; and in the course of his journey, he contracted a cold which brought on a fatal pulmonary complaint. As long as he apprehended no immediate danger, he could not be induced, by all the remonstrances of his friends and physicians, to decline the various sacred employments in which he so much delighted; and he was particularly anxious to complete the transcript of his Family Expositor. He was at length obliged to desist from his labours, and withdrew to the house of his friend Mr Orton at Shrewsbury, where he seemed to be a little recruited by the retirement which he enjoyed. In the autumn of 1751, he was advised by his medical attendants to make trial of the Bristol waters; but the physicians of the place gave him little hope of deriving much benefit from their use; and it was recommended to him as the last resort, to pass the winter in a warmer climate. By the generosity of his friends he was enabled to proceed to Lisbon, and was provided with every possible advantage and accommodation. But soon after his arrival, the rainy season came on with such uncommon violence as precluded all benefit from air or exercise, and greatly aggravated his complaints. On the 24th of October, he was seized with a colliquative diarrhoea, which speedily exhausted his remaining strength; but he still preserved the same composure, vigour, and cheerfulness of mind, which he had uniformly possessed throughout the whole period of his distress. He desired the most affectionate remembrances to be conveyed to his children, his congregation, and his friends in general; and expressed a variety of devout sentiments, which Mrs Doddridge was too much affected to recollect with sufficient distinctness. On the day preceding his death, he lay in a gentle slumber, and at last, having appeared somewhat restless during the space of an hour, he died on the morning of the 26th of October, 1751. Agreeably to his own desire, his body was opened after his death; and his lungs were found in so extensive a state, as to render it surprising that his speaking and breathing had not been more painful to him than they were even to the last. His remains were interred in the burying-ground of the British Factory at Lisbon; and a handsome monument was erected to his memory by his congregation in his meeting-house at Northampton. He left behind him four children, three daughters, and one son named Philip, who was bred to the law, and settled as an attorney at Tewksbury.

Dr Doddridge was not handsome in his person, which was very thin and slender, rather above the middle size, and stooping considerably from the shoulders; but when he was engaged in conversation or in preaching, there was a remarkable sprightliness and vivacity in his countenance and manner. He possessed what are rarely united in one person, great quickness of apprehension, a remarkable strength of memory, and an uncommon application in the prosecution of his studies. He was surpassed by few in the extent of his learning, and the variety of useful knowledge which he had acquired. Though he could not be called a profound linguist, he was sufficiently versed in the learned languages to read with pleasure the most valuable productions of antiquity; and though his disposition inclined him to polite literature, rather than to the more abstruse sciences, he was far from being a stranger to mathematical and philosophical studies. But it was to divinity, in the largest sense of the word, comprehending all the subjects of natural and revealed religion, the evidences of the Jewish and Christian revelations, ecclesiastical history, the writings of the fathers of the three first centuries, and the different systems of theology, that he chiefly applied his mind, and that he attained the highest excellence. The stores of information which he had collected, were well arranged in his mind; his own ideas of the parts which he had studied were clear and distinct; and he possessed an uncommon facility both in speaking and writing upon the subjects with which he was acquainted. Hence, as a preacher, he was often able, when in the full flow of spirits, to speak with little preparation, and with great elocution and effect; and when he employed greater care in the composition of his sermons, his method was perspicuous, and his sentiments naturally arranged. He studied at least to conclude his discourses with an animated and affectation application; and his mode of delivery, like his ordinary style of conversation, was full of vehemence and vivacity. In his younger years particularly he gave proofs of considerable poetic powers; of which his celebrated paraphrase on his family motto, "Dum vivimus vivamus," which Dr Johnson has specified as one of the finest epigrams in the English language, may be given as a specimen:

"Live, while you live," the epicure would say,
"And seize the pleasures of the present day."
"Live, while you live," the sacred preacher cries,
"And give to God each moment as it flies."

Lord, in my views let both united be;
I live in pleasure, while I live to thee.

Of his moral and religious character, it is scarcely possible to speak in too high terms; and it may almost be affirmed of him in his own words, "that it is hard to say where, but in the book of God, he found his example, or where he has left his equal." His piety was ardent, uniform, and unaffected; and was particularly displayed in the resignation, serenity, and cheerfulness with which he sustained his afflictions. The nearer that his dissolution approached, his impiurnental spirit was the more remarkably conspicuous; till at length he seemed to have completely risen above the concerns of this world, and to be daily breathing after immortality. This devout disposition was accompanied by the warmest benevolence to his fellow creatures, which was abundantly manifested in the most active exertions for their welfare, in his tendency to overrate the merits of others, in his candour and moderation towards those who differed from him in sentiment, and in the mild and forgiving temper with which he bore the most unkind and unmerited treatment. He was distinguished by the humility with which he regarded his own attainments, the condescension which he shewed to the meanest persons, and the patience with which he submitted to the words of reproof. In the private virtues of friendship and domestic life, he was remarkably amiable; and his deportment in company was strikingly polite, affable, and pleasing. He has sometimes been blamed for the accommodating style of his language in addressing persons of different sentiments, the over complimentary strain of his epistles, the fondness which he shewed for universal applause, and the ostentation with which he sometimes spoke of the multiplicity of his engagements; but notwithstanding these slight imperfections, (and they are all that
DODDRIDGE was ever laid to his charge,) he must be acknowledged, in the words of Dr Kippis, to have been "not only a great man, but one of the most excellent and useful Christians and Christian ministers, that ever lived."

Besides carrying on, during his life, a most extensive correspondence, sufficient to have occupied the whole of most proposers, and publishing a number of occasional sermons and smaller pieces, which, under the title of "Tracts," form three volumes 12mo, Dr Doddridge, by his strict economy of time, found means, amidst his abundant labours as a tutor and a pastor, to produce, as an author, a number of works, which have been very highly and generally esteemed. In 1732, he published Sermons on the Education of Children, which contain, within a small space, many important considerations for the encouragement of parents in this momentous duty; and in 1733, seven Sermons to Young People, which have been equally well received. In 1736, appeared his Ten Sermons on the power and grace of Christ, and the evidences of his glorious Gospel; the three last of which were afterwards printed separately, and were successful, among other instances, in convincing the minds of two gentlemen of liberal education, who had been sceptical on that subject. In 1739, he presented to the public the first volume of The Family Expositor, which may be considered as his great work, and the dedication of which, to the Princess of Wales, has been pointed out as furnishing one of the best specimens of his talent for elegant composition. In 1740, appeared the second volume of the same work; and in 1741, a course of Practical Discourses on Regeneration, which have been justly characterized by a foreign divine as uniting orthodoxy with moderation, zeal with meekness, and deep-hidden wisdom with uncommon clearness; as displaying simplicity without coldness, elegance without painting, and sublimity without bombast. In 1745, was published one of his most popular and useful works, The Rise and Progress of Religion in the Soul, which was written at the request of Dr Isaac Watts, and which, besides obtaining the high commendations of many eminent established clergymen, and an extensive circulation in this country and America, was translated into the Dutch, Danish, French, and German languages. In 1747, he published Some remarkable Passages in the Life of the Hon. Col. James Gardiner, a work of which many of his literary friends, and the learned Warburton in particular, expressed the most unqualified approbation. In 1748, appeared the third volume of The Family Expositor; and in the course of the same year, he revised the expository works and other remains of Archbishop Leighton, and translated his Latin Prayers, an employment in which he declared that he experienced the highest edification and delight. Of The Family Expositor three volumes remained to be published after the death of the author, but the whole had been finished in short hand, excepting a few notes at the conclusion; and the greater part, especially the whole of the fourth volume, which was published in 1754, had been actually transcribed for the press. In 1755, Mr Orton published a volume of hymns from the pen of Dr Doddridge, which have been generally acceptable, and have passed through numerous editions. In 1756, the same gentleman published the fifth and sixth volumes of the Expositor; and thus completed a work on which the author had bestowed the greatest care, and on which his literary reputation chiefly depends; a work which continues to be held in the highest estimation, and which has eminently contributed to the instruction and improvement of the Christian world. The last work of Dr Doddridge, given to the public, was his Course of Lectures on the principal Subjects of Physic, Ethics, and Divinity; with References to the most considerable Authors on each Subject; and was published in 1763 by the Rev. Samuel Clerk of Birmingham, the son of the author's earliest benefactor. Another edition, improved by new and appropriated references, was published in 1794, in two volumes octavo, by Dr Kippis. Upon this work, which was formed upon the plan of Mr Jennings, Dr Doddridge employed much of his time; and, to the last moment of his life, he continued to enrich it with additional remarks. See Biog. Britannica; Orton's Life of Dr Doddridge; and Letters to and from the Rev. P. Doddridge. (q)

DODECAS, a genus of plants of the class Dodecandra, and order Monogynia. See Botany, p. 223.

DODECATHEON, a genus of plants of the class Pentandria, and order Monogynia. See Botany, p. 136.

DODONA. See Oracle.

DODONÆA, a genus of plants of the class Octandria, and order Monogynia. See Botany, p. 204.

DOFAR, or DAFAR, is a seaport town of Arabia Felix in the province of Hadramaut. It is called Hamme Badgerey by the natives, and is situated about 50 leagues from Cape Fortash. The town is small, and the anchorage is about two miles from the shore. Dofar was formerly a place of importance, but was destroyed by the Portuguese in 1526. The principal article exported from Dofar is incense, called olban, or liber, but it is greatly inferior in quality and virtue to that of India. Provisions and refreshments cannot be procured here. The natives, who are shy, though not unfriendly to strangers, are armed with matchlocks and spears. East Long. 54° 33', North Lat. 17°. (r)

DOG. Among the various animals which have been rendered subservient to the human race, the dog ranks high in utility and importance. Recurring to the earliest stages of society, we find that, by means of its fleetness, courage, and sagacity, creatures the most ferocious were subdued or obtained for domestication; that it has ever contributed to procure subsistence for man, to watch his personal safety, and to protect his property. If we are not now equally sensible of the advantages resulting from its aid, it is because other substitutes have rendered it less essential.

The dog belongs to the genus canis of Linneaus; but at this day the species are so much multiplied, and so diversified in colour, size, and appearance; the gradations so slight and innumerable, that it is difficult, if not totally impracticable, to confound on those possessing exclusive characteristics. Neither should we find it an easier task to ascertain the primitive stock from which one or more of the races has sprung; for although celebrated naturalists have entered on this inquiry, their results are vague and unsatisfactory. Caius, Linneaus, and Buffon, have all presented a tabular view of their origin and relations; yet none having seen that origin, nor having experimentally proved what are the consequences of intermixing species assumed as distinct, and besides being all at variance in their conclusions, we are precluded from adopting the sentiments which they entertained.

The dog is nowhere known to live in the natural state. From periods of the most remote antiquity it has been associated with man; and in those countries where troops run wild in considerable numbers, they constitute the descendants of domesticated dogs, which, during a few antecedent generations, have lost their masters. But the habits of these, which undoubtedly approach nearer to the original condition of the animal,
The dog is entirely a carnivorous animal, and in feeding tears its prey. Farinaceous substances are readily received; but roots, leaves, or fruits are less acceptable, and the bones of most wild fowl rejected. The natural nature of the animal ever betrays itself in seeking, and ravenously devouring, flesh when it can be obtained. Its teeth are calculated to break down the hardest bones in splinters, which are digested in the stomach: and, like most animals whose success is uncertain in capturing prey, the dog can survive a long time on a very slender supply. It drinks, as is well known, by lapping a fluid with its tongue; but it appears to us that this is accomplished by the inverted curvature of the organ, that the fluid is taken up in the edges below, and not by the upper surface of the tongue.

The female carries her young between sixty and sixty-three days: they are blind during nine days after their birth, from a membrane uniting the eye-lids, and not from the imperfection of the eyes. It is said that a repetition of the sexual union does not augment the number of young; an assertion which it would be difficult to prove, though it is extremely probable, that the conception of females is immediate, perhaps instantaneous. It might more correctly be advanced, that several puppies are frequently the result of a single union; and an instance has been given, where the mother, a pointer, having received two dogs of different descriptions, a terrier and a greyhound, she produced two pointers, two terriers, and two greyhounds; the first and last of which proved excellent dogs. The number of young is exceedingly various, being from one to seventeen; which is the largest well authenticated litter that has come within our knowledge, and was the offspring of greyhounds. Generally the litter is between four and ten; most of which we are accustomed to destroy, from supposing the safety of the mother would be endangered by rearing so many young. Possibly the dog is greatly affected by domestication, but in all other situations, nature has enabled the parent to provide for the offspring.

Various other characteristics are given of the dog by different naturalists; such as the tail inclining to the left; the animal running obliquely, resting on the toes, going frequently round the place on which it designs lying down, advancing before its master on a journey, and if the road divides, looking back. But the modifications which the disposition and habits of this animal undergo in an artificial state are so important, that we cannot assume from them what would be its untamed nature. It has been observed, however, that those which have been long emancipated from human dominion, have, to a certain extent, resumed the properties of their race. Their ears are always erect, their sight piercing, and their smell acute; they live in numerous societies, refusing the intermixture of any stranger breed; they hunt in concert, and their voice is seldom heard, unless when in pursuit of prey: they then venture to attack the strongest animals, and repose immediately on the exertions which have procured them sustenance.

The dog, the wolf, the fox, and jackal, are all intimately allied in structure and habits. From some unsuccessful experiments in obtaining young from the dog and the two former, it was believed that they were of different genera; but later observations prove, that this intermixture is practicable; and we certainly see dogs which seem to betray their origin from a less domesticated animal.

Naturalists in general have endeavoured to trace all the varieties of the canine race to one parent stock, which is more commonly thought to centre in the shepherd's dog, so called from always being chosen as the guardian of the flock. This species is pre-eeminently distinguished by sagacity; and those of a genuine breed scarcely require education, for even while puppies they have been seen instinctively collecting the sheep around their master's feet. In South America, Don Felix Azara acquaints us, that they are removed from the mother while blind, and nursed on different ewes; they take the flock to pasture in the morning, and return with it to the fold at sunset. The shepherd's dog is of a middle size; the muzzle rather slender; the ears short, pointed, and erect. The whole body is remarkably hairy, particularly the hips, but the face is smoother than the rest; its covering is calculated to resist the elements. The tail is of considerable length, and bushy; and the colour of the whole animal is black, brown, or modifications of both. Buffon affirms that in France the former is predominant; we believe that it is not so in Britain. Since the days of that naturalist another species has been discovered, which certainly tends to corroborate his theories respecting the aboriginal stock; we mean the dog of New Holland, called Dingo by the natives. Considering the separation of that vast continent from all the civilized parts of the globe, the rudeness of its inhabitants, estranged from every art and improvement; and also, that scarcely any animals dwelling upon it have been recognised in a different region, it is not unlikely that the dog may have been preserved in greater purity, or perhaps altogether free from intermixture for many successive generations. Only a single species has hitherto been found corresponding in every thing excepting size; and on comparing the figure given by Mr White, Governor Phillips, and also on attending to the minute description by M. Frederic Cuvier, the resemblance to the shepherd's dog is at once irresistible.

The New Holland dog is nearly two feet high, the colour dun, but much lighter on the under part of the neck, breast, interior of the thighs, and muzzle. The tail is long and bushy, depressed when the animal listens, at other times elevated or carried straight. As in those animals exposed to the intemperance of climate, the hair close to the skin is short, fine, and woolly; and above, longer and coarse. The ears are short, erect and always pointed forward; and the head is carried high. It is distinguished by great muscular power, and uncommon boldness, readily attacking all other dogs, when opportunity admits: its nature is remarkably savage, and unlike those of the old continent, the domesticated dog of New Holland seems irreclaimably vicious. It seldom barks, and even does so with less facility than the other dogs familiar to us. We are unacquainted with the mode of its propagation, and whether it is ever found without a master, which is the genuine state in which its history is to be studied. Some have been brought both to France and Britain, which ate raw meat with avidity, but always rejected fish, and however agile on the land, proved incapable of swimming.

Except in size, the skeleton of the dog of New Holland can scarcely be distinguished from that of the wolf; the teeth are the same in number, the relation of the bones of the head intimately correspond, the vertebrae of the tail consist of thirteen in both, and there is an
equal number of toes on the feet. The head of the jack-
al being nearer the size of that of the dog of New Hol-
land, presents as striking a similarity; and the principal
difference either in it or the head of the wolf, is seen in
the greater or lesser distance between the cavities of
the eyes. But in comparing the heads of other dogs
with the head of this species, that of the Irish grey-
hound bears the nearest resemblance; and the cranium
is somewhat more capacious in the great Danish dog
and shepherd's dog. Those three Buffon considered
as the primitive races, modified into every variety, by
intermixture and climate.

We find it vain, however, to follow that author, or
indeed any other, through all the varieties of an animal
which breeds promiscuously, and has done so for ages
inmemorial, with every kind and description of its
species, thus adulterating what might have been or-
iginal characters: We shall therefore only notice a
few concerning which there is little room for dis-
pute, and speak of the properties of the dog in general.
Besides, the confusion in which the natural history of
the animal is involved is so great, that we could not at-
tempt to extricate it from error, without engaging in
dry and tedious discussions.

Dogs are extremely various in size, from the Irish
greyhound, Danish dog, or mastiff, down to the small-
est lap dog, not equal to one half the head of any of
them. Brown seems the predominant colour; almost
all others, except red and green, occur in every dif-
ferent shade, but we do not know any instance of these,
though they may possibly be seen elsewhere. Dogs,
confessedly of the same species, are of opposite colours.
Blueish, or slate grey, are less common than others;
black, or brown speckled with white, are rare; and
wherethewholebodyisspotted,large spots are more ge-
nerally disseminated than small ones. These observations,
however, are liable to every modification imaginable,
and localities may have rendered the distinctions more
prominent, by the preference for a certain colour in a
breed, or the partialities of the place.

The Irish greyhound is said to derive its name from
Ireland, where it is now almost extinct, and is one of
the largest of the race, if not exceeding the whole in
size. If we are to credit Dr Goldsmith, some were
known, when he wrote, four feet high, or the size of a
calf a year old; and Buffon says he saw one which
seemed nearly five feet high when sitting; it resembled
the great Danish dog in form, but differed from it in
the enormity of its size; it was entirely white, and of
amild and quiet disposition. More recently, a descrip-
tion of the Irish greyhound has been given by Mr Lam-
bert, who saw eight of these animals in possession of
Lord Altamont, in the year 1790, and they were the
sole remnant of their race, which had then degenerated.
The hair was short and smooth, brown and white, or
black and white. One of the largest dogs was 61
inches long from the muzzle to the point of the tail,
which latter was of itself seventeen inches and a half in
length. The ears were six inches long, and pendulous.
The height from the toe to the top of the fore shoulder
twenty-eight inches and a half; the circumference of
the breast thirty-five inches, and of the belly twenty-
six. All were good tempered; and in former genera-
tions they are said to have bore greater resemblance to
the greyhound. According to Daubenton's measure-
ments of the different parts of the dog, these dimensions
present the greatest analogy with those of the great Da-
nish dog. By the name matin, it is rather to be inferred
that Buffon means the Irish greyhound; but it is diffi-
cult to reconcile his description of it with the animals
now alluded to.

We are not aware that the great Danish dog, though
Great Dan-
not uncommon on the continent, is frequent in Britain, nish dog.

It is particularly distinguished by its size, and, accord-
ing to Daubenton, is chiefly of a brown colour. Buff-
on considers that this dog, the Irish greyhound, and
the common greyhound, are "only the same animal,
though at first sight different. The great Dane is but
an Irish greyhound (matin) better filled up; the com-
mon greyhound, the latter more delicate and slender,
and better treated. There is no greater difference
among the three, than between a Dutchman, a French-
man, and an Italian."

The small Danish dog, leopard, or spotted dog,
which has been lately propagated with considerable
care in Britain, to attend carriages, differs little from
the former, except in size and colour; and although
Daubenton endeavours to prove it a distinct breed, his
reasons are inconclusive. Aldrovandus affirms, that its
trivial name was brachus, and that it was preferred
when spotted like a lynx, although those of uniform
colour were not to be despised. Buffon calls it brachis
dec Bengeale, whence the real derivation of the race is
not to be traced, especially as we observe, in the
older writings in this kingdom, hunting dogs are called
brachis et rachis: Caius says, the latter was applied to
blood-hounds, in Scotland.

The common greyhound is well known from its use
in the chase, and the breed seems preserved in greater
purity than that of most other varieties. It is said
there are three different kinds distinguished by size,
and we find them either rough or perfectly smooth.
It has long been a celebrated dog in Britain, and Mr Strutt has quoted passages to prove that it formerly con-
stituted a valuable and acceptable present. The Itali-
an greyhound narrowly resembles that animal in propor-
tions, and some authors think it is the same degener-
ated. The greyhound is much employed for coursing
or hare hunting in the Greek Islands. Analogous to
this was the gazehound, of which we know very little,
except that it was used in the pursuit of deer; but
whether it was a distinct variety, or only a greyhound
of the largest size, is doubtful; for appellations nearly
the same have been bestowed on dogs, specifically dif-
erent; neither is it evident whence the name is de-
rived. It has been affirmed, that the badger was an-
ciently called a grey, and from this particular species
being used in hunting it, the name was thence bestowed;
however, we cannot subscribe to that etymology, as it
does not rest on repeated example; but in Scotland the
greyhound is simply called a grove.

The bloodhound, foxhound, harrier, and beagle, had
most probably nearly an analogous origin, and have
long existed both on the Continent and in Great Brit-
ain. Few, if any genuine descendants of the first still
remain in this island; the others are not uncommon,
and care is taken to preserve those of the most decided
qualities for the chase. The last is the smallest variety
of hounds.

Pointers are of different kinds, either approaching the
Pointers, pike or appearance of the Danish dog, or being long-
headed setters, as they are commonly called. For centuries,
the English setter has been much esteemed on the Con-
tinent. Caius, in his description of the dogs used by
fowlers, mentions three kinds, the spaniel, the setter,
and water spaniel or finder. This last is the grand
barbet of Buffon, entirely covered with long curled
hair, its ears large, pendulous, and the eyes concealed.
by the roughness of the face. Analogous properties are displayed by dogs externally of very different species in pointing at game; for the English or Spanish pointer, a smooth, robust dog, with a thick muzzle, bears no resemblance to the silky-haired delicate-looking English setter; and again the cocker or springing spaniel seems intimately allied to the latter, whose chief quality is raising the game.

The Turkish or Barbary dog is remarkable for being entirely naked, and destitute of hair; the skin is of a brownish flesh colour. Aldrovandus says, that the first seen in Europe were brought to Italy during his own time, where they were incapable of subsisting or propagating, on account of the cold; and the same observation has been made with respect to those carried to France. Dogs in the warmest climates are frequently destitute of hair, which some authors maintain results from the heat affecting their nature; but others think it is in consequence of the species being different; and Azara remarks that the dogs of South America are both rough and smooth. The origin of the Turkish dog is uncertain, at least it does not frequent all parts of Turkey; and Somnini affirms, that he never met with any of the species there, nor could he learn that it was known in the country.

The turnspit is distinguished by a low, long body, and the fore feet turning outwards, which last peculiarity is wanting in two varieties. The terrier is said to be of two or more kinds; the English, a smooth black or brown dog, generally with a spot above each eye; and the Scotch, smaller, rough, and commonly white. Probably both are of mongrel breeds; as it is likely all, or almost all, the others are, though they be considered of a specific family.

Besides these, there are many other races of dogs enumerated in the Systema Naturae and elsewhere, particularly in the older writings, relative to the chase, but so insufficiently characterised, as absolutely to preclude a history of all the individual species. The Systema includes thirty-four, besides two additional turnspits, and a Peruvian dog. Cains, in the sixteenth century, enumerated sixteen English dogs, distinguishing each by its Latin and English name. Daubenton describes sixteen principal, five secondary races, resulting from the intermixture of the former; and five more the offspring of the mongrels. Thus we shall only observe, that, in addition to those we have mentioned, there are among others, the Pomeranian wolf dog, Siberian and Iceland dog, all allied to the shepherd’s dog, and approaching it in size. The lurcher, rough lurcher, and boar lurcher, which are ill-defined. The Maltese and King Charles’ dog; the mastiff and bull dog. Neither of the latter seems from a pure breed; the pug dog is said to be a diminution of the bull dog; and what we call German poole, seem the mongrel offspring of the great water spaniel. Cains mentions a mongrel called rope, which is probably a breed from the shepherd’s dog, but now known as the colley, whappie, or cur dog in Scotland and England.

In a general view of the nature and disposition of the dog, we find it materially affected by the habits of that portion of mankind among whom it dwells. It undergoes a sensible modification. Vicious and ferocious among savage tribes; gentle and docile with those that are humanized. No animal is of equal docility as to the dog. By a kind of intuitive faculty, he soon learns to distinguish the friends of his master’s family, while his own attachment to him remains unimpaired; they are courteously welcomed to his dwelling, but strangers are angrily repulsed. The animals around him are treated as his master would treat them. A natural enemy to wild beasts; the kitten, the fawn, and the leveret, domesticated along with him, become objects of terror. He is tractable and compliant, subsisting in patience to his master’s resentment, and forgets all his pains in the joy of being restored to a place in his favour. It is from this docility and fidelity of the dog, that mankind have derived the principal services which are now exacted from him: that he has pursued the beasts of the forest in concert with the rudest of our ancestors; or has watched the drawing of the net, or the deadly aim of the more civilized sportsman. Nor is it in aiding the acquisition of subsistence only, that his use is most conspicuous; he boldly stands forward the first to defend it, and is the faithful guardian of the night, whose vigilance never sleeps.

It is not to be denied, however, that amidst the benefits derived from dogs, some may be differently esteemed in different ages. We read that of old, when possessions were insecure, the blood-hound was employed to trace out the thief, and recover the stolen goods; that he would swim a river in course of the pursuit, and immediately discover the footsteps of the culprit on the other side, never ceasing to follow him until he was taken. Thus this animal is put under the protection of the most ancient laws, which enact, that “no one should disturb or stop a blood-hound or man passing with him, to follow thieves, or take malefactors.” Theft was also so common in this island, that a person denying access to the hound, was to be held participant in the crime. There is little doubt that it was known on the continent, and also in England; but the Scottish blood-hound, which is said to have been of large size and elegant proportions, was the most celebrated of all. Conrad Gesner, who wrote nearly 300 years ago, has preserved a figure of the Scottish blood-hound, which he says was transmitted to him by Henry Sinclair, dean of Glasgow, a distinguished character of his era; and Hector Boyce affirms, that it was of a red colour, or black with small spots. There was some difference between it and the English blood-hound, though the properties of the latter were also eminent. Mr. Boyle, in his Treatise on the Air, relates, that having heard wonderful accounts of the acute sense of smell in the Irish hounds hunting wolves, he was induced to make further investigation into the subject; and he was told that the English blood-hound could follow a man by the scent some hours after he had passed over the ground. A relation of his also informed him, that he had expressly made an experiment on the subject, by sending a servant, who had neither killed a deer, nor even touched one, to a certain village four miles distant, from whence he was to proceed to a market-town three miles farther. When the servant had advanced about half way, the dog was let loose, and pursued his footsteps, disregarding all other people in the way; and in the same manner passed through the crowd in the market-place, intent on the object, until coming to the door of a house where the man was resting himself in an upper apartment, and there found him, to the great admiration of all the spectators. We learn from Strabo, that the British blood-hounds were used in the wars of the Gauls; and many centuries later the Spaniards are said to have carried these animals to the continent and islands of America, to aid them in their ferocious attacks on the peaceable inhabitants. There the race is still preserved for its original purpose under other masters, in hunting mankind. In the year 1492, twenty blood-hounds
formed part of the auxiliaries of Columbus, in his contests with the natives of St Domingo. The French, during the recent war in that island, carried on with the revolted negroes, employed blood-hounds regularly trained against them; and they are even said to have had the barbarity of throwing their captives to the dogs to be devoured alive. In training the hounds to this inhuman pursuit, we are told that they were confined in a kennel sparred like a cage, and sparingly supplied with the blood of other animals. The figure of a negro in wicker work, stuffed with blood and entrails, was next provided as they grew a little older, and occasionally exhibited in the upper part of the cage: the dogs ferociously struggled against their confinement, and, as their impatience increased, the effigy was brought nearer and nearer, while their usual subsistence underwent still greater diminution. At length it was resigned to them, and while vociferously tearing it up and devouring the contents, the caresses of the keepers encouraged their perseverance. Thus their animosity to black men was excited in proportion to their attachment to the whites; and they were sent out to the chase when their training was considered complete. The miserable negro had no means of escape: he was either hunted down and torn to pieces, his wife and children perhaps sharing his calamity; or, if taking refuge on a tree, he was betrayed by the yelping of the blood-hounds into the power of his more savage pursuers. This, however, was not the full extent of the evil. "But differently kept in the neighbourhood of Cape François, the dogs frequently broke loose, and infants were devoured in an instant from the public way. At other times they proceeded to the neighbouring woods, and surprising a harmless family of labourers at their simple meal, tore the babe from the breast of its mother, or devoured the whole party, and returned with their horrid jaws drenched in the gore of those who were acknowledged even in the eyes of the French army as innocent, and therefore permitted to furnish them with the produce of their labours." The stages of cruelty are progressive; and those who delight in the torture of animals, will soon be indifferent to the sufferings of mankind. Accordingly, the rude nations universally enjoy ferocious contests, and are gratified with the sight of blood. Lions, tigers, and elephants, have been encouraged to tear each other in pieces, where mutual antipathies ceased to operate; and bulls have been fought against dogs in this country since the days of Claudian. But in the present age, we may be surprised at the toleration of a practice, alike abhorrent to humanity, and inconsistent with the feelings and manners of the British nation. If the baiting of bulls was sport to our ancestors, it certainly ought to excite nothing except commiseration for the pain of an innocent creature, and disgust at the barbarity of those who can enjoy it. In the reign of Henry II. bull-baiting was an amusement of the London populace. Nay, much more recently, Queen Mary entertained the French ambassadors two successive days with an exhibition of this kind in the year 1559. Queen Elizabeth, her sister, repeated it to the ambassadors from Denmark in 1586; and, what is more extraordinary, the queen was herself among the spectators. Paul Hentzner still later describes the cruel diversion of the English people, to whom the baiting of bulls, bears, and badgers, was familiar; and there is even reason to believe that the horse was sometimes publicly worried to death, to glut their savage appetites for a brutal spectacle.

On all these and similar occasions, such as when a bull, jointly pursued by the dogs and their masters, was hunted down or bruised to death with clubs, the minstrels, a miscreant crew, claimed the slaughtered animal as a perquisite. It is long since the worrying of bulls in the streets of London was prohibited, but the practice was widely extended, and the rings to which the bull was chained for the certainty of undergoing aggravated torment, are still extant in many towns and villages, where they are sometimes converted to use. Posterity will scarcely credit, that only a few years have elapsed since this savage custom was defended in the British Parliament, as an innocent recreation, contributing to the health and well-being of the community. But let us leave such prostitution of the courage and fidelity of so valuable an animal as the dog, to consider the benefits conferred by its domestication on mankind.

From a very ancient period, dogs have been converted into beasts of burden, and yoked in harness to carriages; and down to the present day, they are trained to the same services on the Continent of Europe, in Asia, and America. But it is in the frozen regions of the north, where the utility of the dog is so eminently displayed, and where travellers, by its assistance, are enabled to cross trackless deserts of snow, otherwise impassable. Marco Polo, a celebrated Venetian of the thirteenth century, distinctly speaks of a country in the north of Asia, difficult of access on account of the intermediate mud and snow, from which great quantities of furs were carried in vehicles wanting wheels, by means of dogs. The information he received on the subject characterizes the sledges of Greenland or Kamtschatka, now drawn by these animals. In this latter country, the species employed is of a middle size, of various colours, white, black, grey, or black and white, of wolfish aspect, yet not unlike the shepherd's dog, or its mongrel offspring. Its hair is rough, its tail recurved, and the ears pointed; it cannot be taught to hunt, and never barks but howls. Though regularly trained to the draught, the dog of the Kamtschadale and Greenlanders seems less tractable and domesticated than that of civilized countries, proving, perhaps, how much its nature is modified by associations with man. All that are thus occupied are castrated, to preserve them more under control. During the prevalence of ice and snow, from five to ten are harnessed to a light sledge of wicker-work, about three feet long, and one in breadth. The driver is supported by a seat a yard above the ground, and the whole frame rests on two curved pieces of wood, or sometimes whalebone, which operate as skates in gliding over the frozen snow. The total weight of the sledge does not exceed ten pounds, in which journeys incredibly long are safely accomplished. The harness is made of leather; the dogs are arranged in pairs, commonly with a leader of the whole in front, and are fastened together by straps or reins through their collars, fixed by a hook and chain to a ring in the fore part of the sledge. If the journey be difficult, or the burden heavy, the number of dogs is increased; and when M. Lesseps brought the dispatches of La Perouse over land from the harbour of Petropavlovski, 37 dogs were harnessed to his sledge, and 45 to that of the companion of his journey, the governor-general Kasloff. Thirty-five sledges were in company, drawn by nearly 300 dogs. But journeys of this description, though generally successful, are not entirely void of danger. The traveller, whose position is sidewise, and not directed forward, must be careful to preserve the equilibrium of so slight a vehicle; if it inclines to the right, he
must lean to the left, and his posture must be changed when the inclination is reversed. The utmost vigilance is necessary not to be overstept; and if this accident should occur, he must hold vigorously by the sledge, as the dogs once in motion run straight forward, and with greater ardour on the burden being lightened. They are scarce to be restrained on the open way, and on descending steep declivities, Krasseninokoff affirms that all except one are unhked, from the violence with which they rush down. They likewise become unruly on scenting deer, or hearing dogs in the neighbouring villages. Much of the security of the traveller depends on the training of the leader, and the whole are guided by the voice and a crooked stick, without any whip. But the fatigue of long journeys is so great, that the dogs frequently perish under it; food is scanty, and shelter rarely to be obtained. Of the 300 dogs employed by M. Lessep's party in crossing the peninsula of Kamtschatka, only twenty-seven at last remained; many died of want and exertion; others when tied up ate the cords and harness from hunger; and some dived the carriage wheels to which they had perished. Nevertheless, their speed, strength, and patience of privations, are remarkable. Egeden, the Danish missionary, affirms, that the dogs of the Greenlanders sometimes drags a sledge fifteen German, or about sixty English miles over the ice, in a day, and Captain King relates, that a courier performed a journey of 270 miles by means of them, in less than four days. Yet these animals are very sparingly fed, and in summer altogether neglected. At that time they are turned loose to provide for themselves, when they catch fish and dig for mice: they are recalled by their masters in October, when well fattened, by their liberty, and tied up near the huts, until becoming leaner and better adapted for the draught. Only a small proportion of the whole remain unmuti lated, for the purpose of preserving the breed.

Lipsins, an author of the sixteenth century, tells us, that a dog, apparently the English mastiff, was used in his youth, at Brussels, to draw carts laden with hides to market; and that dogs were even sent without a master to bring commodities. This has been continued in Holland down to the present time; and dogs are constantly seen drawing men, or loads of fish and provisions, in vehicles adapted to their size. In Canada also they are occupied in drawing a small cart or sledge, heavily laden, not less than 200 pounds being sometimes dragged along by a single animal. Wheel carts are used in summer and sledges in winter, all proportioned to the size and strength of the creatures yoked to them. There is said to be no particular species, but all sorts and sizes are thus employed, in dragging children, water from the rivers, and other things for domestic purposes. In Newfoundland, dogs are occupied in drawing down quantities of wood on sledges to the sea, from the interior, and being generally large, they are capable of more severe labour; but they are so well trained, as to perform it without the guidance of a master. Of late years, a few are likewise used in England, to draw incalculable weights.

Instances of docility. We are daily presented with wonderful examples of the docility of animals; but none is so universally susceptible of education as the dog. He is more the natural companion of man; his attachment is warmer, his fidelity more unshaken: he is ever alive to the interests of his master, and seems to have no enjoyment equal to his society. It is not surprising, if a creature possessing such properties, has sometimes been rewarded with reciprocal regard: and that unusual care should be taken to teach him, in preference, peculiar feats of address, which seem denied to the powers of others. Our limits prevent us from here entering on what would be an amusing narrative, except to remark, that Plutarch has preserved an account of a dog exhibited to the emperor Vespasian, which has scarcely been rivalled in any example of modern tuition. This dog belonged to an actor; and nothing could be more skilful in scenic representation, and in imitating various circumstances and situations. It exhibited in itself the execution of a malefactor, feigned the taking of poison, and the tremor following its sudden operation; then, falling down, its limbs were stretched out in perfect resemblance of death; and so it remained for a certain time, until, by a word from its master, it gradually opened its eyes, looked languidly around, and at length recovered. But in the course of last century, an exhibition somewhat similar took place in Britain, where the storming of a fort was imitated by dogs, attended by the feigned destruction of some of the party; and we have witnessed the performance many times by these animals, such as the solution of arithmetical questions, the selection of certain cards, from a pack spread out, to denote the hour of a watch. A dog has also been taught to carry a glass of wine on a salver without spilling it, in which we are reminded of a female wolf, shut up with a companion, that could take up a platter of food with her teeth, and run round the kennel, preserving the whole in safety. The account of a dog that was taught to speak, which has often been incorrectly referred to, should not be omitted here; and we shall quote the original description entire from the memoirs of the French academy. "Without the testimony of such a person as M. Leibnitz, an eye witness, we should not have ventured to mention, that near Zeitiz in Misnia, there is a dog which speaks. It belongs to a peasant; is of the most ordinary kind, and of middling size. A young child having heard it utter some sounds, which he thought resembled German words, took a fancy to teach it to speak. The master, having nothing better to do, spared neither time nor trouble; and happily the pupil had dispositions difficult to be found in another. At length, after some years, the dog could pronounce about thirty words, among which were tea, coffee, assembly, adopted from French into the German language. Its tuition commenced when it was three years old. The expressions of its master are only echoed, that is, after he has pronounced a word, he compels it, apparently unwilling to follow his example, though no severity be required. We repeat, that it has been seen and heard by M. Leibnitz." Certainly this is a very astonishing faculty; but the account of the French academicians, derives support from other examples, though, it must be acknowledged, that the circumstances are not detailed with sufficient distinctness and accuracy.

The speed and energy of the dog are very great. Speed. The distance which it can travel without repose is almost incredible. Fox-hounds in the chase, and pointers in pursuit of game, cannot traverse less than from 100 to 150 miles in a single day; and we have seen that those of a Kamtschatkafalour carried their burden 270 miles in three days and a half. It cannot have escaped notice, that a terrier frequently accompanies our mail coaches, at the same rate during a stage or more. We have instances, well authenticated, of a fox-hound running four miles in seven minutes, or at the rate of thirty-four miles an hour; and experiment has proved, that the speed of the greyhound equalled
that of the swiftest race horse. For dogs, possessed of properties such as these, the lovers of rural sports in Britain have been content to pay extravagant prices. Four hogheads of claret were not long ago exchanged for a foxhound as its value, two hundred guineas were given for a brace of pointers, and L.153 for a single greyhound.

The ancients ate puppies as a delicacy, and they offered them in sacrifice to their gods. Dogs are generally an article of food in the South Sea islands, and provided to regale the visitors of the inhabitants. In various parts of Africa, they are held in like estimation; and in the kingdoms of Whidaw and Dahomy their flesh is exposed for sale in the public markets. In different foreign countries the skin is used for clothing, and at home the finest leather is prepared from it. Neither have the different parts of the animal been judged void of medicinal properties: the fat was formerly thought to be an excellent vulnerary; and an oil or balsam extracted from puppies, by roasting or boiling, was dealt out as a powerful remedy for strains, contusions, and muscular debility. Quacks and empirics, resting their nostrums on the credulity of mankind, find a specific in every thing.

The dog, in common with other animals, is subject to multiform diseases, of which the most dreadful is madness; more dreadful than those afflicting the rest of the brute creation, because a fatal wound may be communicated from it. The most usual symptoms are said to be dulness, loss of appetite, and in particular a departure from the animal's ordinary habits. If a stick, held out by a person with whom it is familiar, excites resentment, this is reputed an infallible criterion. But the dog still continues tractable, and the persons generally around it are the last in danger of attack. Its voice next participates more of a continued howl, with the head elevated in the air; great anxiety appears; it labours under apparent suffering, and testifies the strongest impatience of control. At length it eagerly hurries from the home to which it has always been attached, it bites every animal in its way, its pursuit is incessant of all except mankind, for they are more rarely the objects of injury; and when worn out with wandering, it will sometimes return. If escaping intentional destruction, the dog seldom survives the fourth or fifth day, refusing all food, and dying raging mad. It is a lamentable fact, that a mortal malady, known by the name of hydrophobia, may be imparted by the bite of a dog indisputably rabid; but this distemper does not invariably ensue; neither ought it to be correctly designed the dread of water, for some dogs lap that fluid readily, from the fever affecting them, though they are unable to swallow it. Instant excision of the wounded part is always considered prudent where it may be safely performed; and of late excessive bleeding, such as repeatedly deprives the patient of sense and motion, seems to have been practised with success.

The dog is a long-lived animal; twelve or fourteen years being its usual age, but some reach twenty. All the marks of age are long before conspicuous; the hair alters, the eyes grow dim, the hind legs become paralytic; weakness and extenuation terminate in death. See Pliny Hist. Natur. lib. viii. Strabo, lib. iv. Ælian. de Natura Animalium. Aldrovandus de Quadrupedibus digitatil, &c. lib. ii. Conrad Gesner Icones animalium, p. 25. Caius, de canibus Britannicis, ad Gesnerum var. loc. DOIRE, one of the six departments of France into which the principality of Piedmont was divided in 1802. See PIEDMONT.

DOLA. See ARABIA.

DOLE, the Dola Sequanorum of the ancients, is a handsome town of France, in the department of the Jura. It is the largest town of Franche Comté except Besançon, and was once the capital of the province, and the seat of its parliament and university. The town is situated in a fertile plain, on the right bank of the river Doubs. It was once very strong, but the fortifications were demolished by Louis XIV. It has a college, 12 convents, and a hospital. The university was transferred to Besançon by Louis XIV. Dole has a manufacture of hats and hosiery goods, a forge, and a glassworks; and in the neighbourhood there are mines of iron, copper and coal, and quarries of beautiful marble. The surrounding country is fertile, and produces abundance of wine and corn, in which a considerable trade is carried on, which is facilitated by a canal. Population 8235. It is 50 miles south-west of Besançon, and 270 south-east of Paris. (j)

DOLGELLY, or Dolgellau, is a market town of Wales, in the county of Merioneth, and derives its name from dol or dal, and gelli or eelli, a grove of hazel trees. It is situated in a fertile vale, between the rivers Arran and Wnion, and is circled with lofty mountains, many of which are covered with wood. The streets are very irregular, and so narrow as scarcely to admit two carriages abreast. The houses are built of quartz, or limestone, without mortar. They are seldom above two stories high, and have penthouses in front upon piles. The church, which is the neatest building in the town, is built of limetone, and consists of a tower and a large nave. The seats are merely forms. The market-house is a low square building, and the town-hall can scarcely be distinguished from the other houses. The county gaol, which has lately been erected at a small distance from the town, is a strong and handsome building. A considerable trade is carried on here in flannel, a kind of kerseymer cloth, and a woollen cloth called gree, which is manufactured in the town and neighbourhood. Shrewsbury and Liverpool were formerly the principal markets for these goods, but agents now resort to Dolgelly to purchase them. There is here a weekly market on Tuesdays, and six annual fairs. The following is an abstract of the population return for the town in 1811:

Number of inhabited houses, ............ 537
Number of families, ........................ 728
Do. employed in agriculture, .......... 239
Do. in trade and manufactures, ........ 70
DOLCHOS, a genus of plants of the class Diadelphin, and order Decandria. See Botany, p. 277.

DOLLOND, John, a celebrated optician, who has immortalised his name by the great discovery of the achromatic telescope. He was born in Spitalfields, London, on the 10th of June 1706, of French parents, who had fled from Nantes in consequence of the revocation of the edict of that city. In the early part of his life, Mr Dollond wrotht at the loom, but before the age of 15, he had acquired a taste for philosophical and mathematical pursuits, and spent his leisure hours in studying elementary works of science, and in the construction of sun-dials and geometrical figures. In this way he acquired a knowledge of geometry and algebra; and though his opportunities for study were diminished by an early marriage, and the cares of an increasing family, yet his ardour for knowledge was unextinguished, and he contrived, by abridging his hours of repose, to acquire a profound knowledge of optics and astronomy. His attention was also directed to anatomy and divinity; and he even found leisure to acquire the Latin and Greek languages, in order that he might apply himself more successfully to his favourite pursuits.

Mr Dollond, along with his son Mr Peter Dollond, carried on for some time the business of manufacturers; but the extensive information which the son had acquired from his father's instructions, induced him to commence optician. The success with which this plan was attended, prompted his father to join him in his new profession, an event which happened in the year 1752.

After acquiring a practical knowledge of optics, Mr John Dollond directed his attention to the improvement of the eye-glasses of refracting telescopes, and he succeeded in producing an eye-piece of four glasses and sometimes afterwards an eye-piece of five glasses, which greatly surpassed those in common use. An account of these eye-pieces was read before the Royal Society in 1758, and afterwards published in the 4th volume of their Transactions.

The next effort of Mr Dollond, was an improvement of the double image micrometer, or heliometer, which was invented by Savary and Bouguer. This improvement consisted in using two seminacles instead of two whole object glasses, and has already been fully described in our article Astronomy. See Vol. II. p. 724.

Mr Dollond's attention was now turned to the improvement of the refracting telescope, and his labours were crowned, by the invention of one of the finest instruments that has ever been constructed. The various steps by which he was conducted to this splendid result, have already been fully detailed in our history of the Achromatic Telescope, so that we must refer our readers to that article for further information. In honour of this invention, the Royal Society of London presented Mr Dollond with Sir Godfrey Copley's medal. This learned body also elected him a fellow of their Society in 1761, and in the same year he was appointed optician to his majesty. These honours, however, he did not live long to enjoy. While reading Clairaut's theory of the moon, with which he had been intensely occupied for several hours, he was struck with apoplexy, of which he died in a few hours, on the 30th of November 1761, in the 55th year of his age. Mr Dollond left behind him two sons and three daughters; and his business was carried on by his sons and his nephew Mr George Huggens, who took the name of Dollond.

Mr Dollond was a man highly respected in his moral and religious character. "In his appearance," says Dr Kelly, "he was grave, and the strong lines of his face were marked with deep thought and reflection; but in his intercourse with his family and friends, he was cheerful and affectionate; and his language and sentiments are distinctly recollected, as always making a strong impression on the minds of those with whom he conversed. His memory was extraordinarily retentive; and, amidst the variety of his reading, he could collect and quote the most important passages of every book which he had at any time perused." See Dr Kelly's Life of John Dollond, and the articles Achromatic Telescope, Astronomy, Clairaut, Optics, and Telescope. (X)

DOLPHIN. See Ichthyology.

DOME, or Cupola, a kind of vaulted roof or covering, employed in architecture, in the shape of some portion of a sphere, ellipsoid, &c. and frequently constructed of masonry. Domes differ in some respects from common arches, which are cylindric convexities, resting on parallel walls, and having therefore a curvature only in one direction; whereas domes, as also groins, have a double curvature, and derive a degree of stability from this circumstance, which is peculiarly deserving the attention of the architect. We shall treat of this subject under the article Groins, comprehending therein roofs formed upon curvilinear as well as upon polygonal plans. See Groins; and Carpentry, Part II. p. 528. (A. N.)

DOMEA, is the name of a town, situated on a river of the same name, which is the principal branch of the Tunkin river, and discharges itself into the Gulf of Tunkin, about 20 leagues north-east of the former, in North Lat. 20° 50'. The town of Doma is about six or seven leagues from the mouth of the river, is situated on the right hand side close to the shore, and is a handsome place, containing about 100 houses. The Dutch vessels that trade here generally lie before the town, while the English vessels proceed about three miles farther up, and erect bankshaws during the time that they remain. As pilots are necessary to conduct vessels over the bar at the mouth of the river, a number of them live at a village called Batsha, situated near its mouth. The vessels should anchor, and wait for a pilot, when a small island, called Pearl Island, on the east side of the road, is about N.E. and three miles distant; and when a mountain island, called the Elephant, is about N.W. by W. The river is about a mile wide at its mouth. Its depth, in the northerly monsoon, is 26 feet, and in the southerly not above 18. See Milburn's Oriental Commerce, vol. ii. p. 458. (m)

DOMESDAY-BOOK, contains a survey of most of the lands in England, made by the orders of William the Conqueror. The etymology of the name is rather uncertain; some suppose it to be derived from the circumstance that the survey was deposited in a place called Domus dei; but the more probable derivation is from dom, or doom, judgment; because by this survey all disputes respecting landed property, and the tenure by which it was held, were to be decided. The original and proper name seems to have been Dom-boc. There is also some difference of opinion concerning the object which William had in view, in causing this sur-
Some antiquarians supposing that it was merely that each man might know his property, while others contend that it was for the purpose of establishing bounds, and that there was some necessity to cause a survey to be made for the other purpose, as that had been effectually done by Alfred. That this opinion is well founded, a reference to the state and circumstances of the kingdom, just before the survey was made, will probably induce most of our readers to admit. Although William, immediately after the conquest, put his Norman barons in possession of the restricted lands, which they were to hold by the tenure of military service, yet the landed property, which the Saxon nobility possessed, was not held in this tenure; the consequence was, that the old military constitution being laid aside, and no other generally introduced in its stead, the kingdom was nearly defenceless. When therefore an invasion was apprehended from Denmark, William was under the necessity of bringing over a large army of Normans and Britons, the support of whom greatly oppressed the people. As soon as the danger of invasion was over, William resolved to introduce the feudal system over the whole kingdom; and for this purpose he held a great council, as the Saxon Chronicle expresses it, in which he took the advice of his nobility respecting this country, how it should be held, and by what persons. One of the results of this council was the survey contained in Domesday Book; and as soon as it was completed, the king was attended by all his barons at Sarum, where the principal land-holders submitted their lands to military tenure, became the king's vassals, and did homage and fealty to his person. These circumstances seem to prove what was the object of making the survey; and this view of it is farther confirmed by the nature of the survey itself.

In order that it might be faithfully and strictly executed, some of the king's barons were sent as commission- ers into every shire. Their first step was to summon juries in every hundred; these juries were taken from all orders of freemen, from the barons down to the lowest farmers; and they took an oath that they would inform the commissioners what was the name of each manor, who had occupied it in the time of Edward the Confessor, and who held it then; how many hides, how much wood, how much pasture, how much meadow land it contained; how many ploughs were in the demesne part of it, and how many in the tenant- ed part; how many mills, how many fish-ponds or fisheries belonged to it; what had been added to it, or taken away from it; what was the value of the whole together, in the time of Edward; what when granted by the Conqueror; and what at the time of the survey; and whether it might be improved or advanced in its value. They were also required to give in a list of all the tenures of every degree, and to state who had them, each of them had held, or did hold at that time, and what was the number of the slaves; a particular account of the live stock on each manor was also to be returned. When returns respecting all these particulars were made, they were methodised in the county, and afterwards transmitted to the king's exchequer. There are two volumes of Domesday Book; the first is a large folio, finely written on 382 leaves of vellum, in a small plain character, and double columns; it contains 31 counties; the other, which is sometimes called the lesser Domesday Book, is in quarto, written on 450 leaves, in single columns, and in a fair large hand; it contains Essex, Norfolk, and Suffolk; it is supposed to contain the original surveys returned from these counties. In these the live stock is noted. The greater Domesday, compiled from the originals by the officials of the exchequer, omits this live stock, and gives some other particulars with more brevity. The ancient demesne or landed estate of the crown, as given in Domesday, consisted of 1424 manors, in different counties, besides some scattered lands, and farms, and quit rents, paid out of several other manors. From this survey it appears that the boundaries of the counties were not exactly the same then that they are now, since part of Rutlandshire is included in Northamptonshire; and parts of Westmoreland, and Lancashire, are included in Yorkshire and Cheshire. Northumberland, Cumberland, and Durham, are not noticed. Different reasons are assigned for this omission: Hume supposes it arose from their wild uncultivated estate; others, because they contained no terra regis; that the survey was never completed, or that the ravages of war rendered it unsafe. Pinkerton is of opinion, that Northumberland and Durham were omitted, because they were in possession of the Danes; and Cumberland, because it belonged to Scotland; but William seems to have considered Cumberland as belonging to himself, for when he quarrelled with Malcolm the Third, he gave it to Ranulph de Meschines. London is also omitted in Domesday Book. Although the survey was rigid in almost every instance, yet some of the returns are said to have been partial and false. Ingulphus, Abbot of Croyland, says, that with respect to his abbey, the lands were under-measured, and under-rated; and it is said that Ralph Flamard, minister to William Rufus, was so convinced that many of the returns were partial, or erroneous, that he resolved to make another more rigorous inquisition; if this were the case, it never was put in execution. In the orthography of the names, the Norman scribes made many mistakes, setting them down from the Saxon pronunciation. At the end of the Liber Eliensis, (Cott. Lib. Tib. A. 6. 4.) are some of the original rotuli, whence it was compiled for Cambridgeshire; and in the library of the dean and chapter of Exeter, there is a similar survey of the three western counties, an extract from which is given by Hutchins in his History of Dorsetshire. A fac simile, by way of specimen, is given at the end of Morant's Essex; another in the Registrum honoris de Richmond; and a third in Nichol's Leicestershire; that in Hiche's Thesaurus is not well executed. In the Harleian MS. of Elincts Saxon Grammar, the Numerus Hidorum is given more accurately than in the Appendix to Sale's Hist. Angl. Script. That part of Domesday which relates to Wiltshire has been published in English by Mr Wyndham; and that relating to Leicestershire by Mr Nichols. Mr Bawdwen published "Dom-boe," a translation of Domesday for Yorkshire, and such parts of Westmoreland and Cumberland as comprised in the survey; likewise Derbyshire, Nottinghamshire, Rutlandshire, and Lincolnshire, with an introduction, glossary, and indices; but the most complete illustration of Domesday was published by Mr Kelham, under the title of "Domesday Illustrated." In 1777, it was determined by government to print the whole of it, and after much delay, from various causes, this great work is now completed; the commissioners of public records have likewise printed four indices to it. It is still considered as of very high and unquestioned authority, for the establishment of tenures, and in the article of Taillage. Blackstone says, "whether a manor be held in ancient demesne or not, shall be tried by the record of Domes-
day, in the king's exchequer." See Domesday Illustrated, by Kelham. Littleton's History of Henry the Second, vol. iii. 8vo. edition. There are also several curious notices respecting Domesday Book scattered up and down in Nicholl's Literary History of the Eighteenth Century. (w.s.)

DOMINGO, St., or HISPANIOLA, is the second in point of size, and one of the most fertile of the islands forming the American Archipelago; its dimensions have not been accurately ascertained; but, according to the best authorities, it is 170 leagues in length, 30 in breadth in the middle, and about 360 in circumference. By the natives it is called Haiti, or the Highland Country, on account of the hilly nature of its north division. They also give it the name of Quisqueya, or the mother of countries. When it was first discovered by Columbus, he called it Isabella, in honour of the Queen of Spain; but it soon afterwards was denominated St Domingo after the principal city in the island. It is situated among the islands of Cuba, Jamaica, and Porto Rico, from the last of which it is separated only by a channel: it extends from 17° 37' to 29° north latitude, and from 67° 35' to 74° 15' west longitude. Several small islands lie round St Domingo, the principal of which are: Altarde, Saone, Beate, St Catherine, on the south side from west to east; Mone, and Monique, on the south east side; Gaymote and Conve, on the west; and La Tortue on the north side.

This island is divided into two parts; that which is now strictly and properly called Haiti, and Hispaniola; the former comprehends the ancient French division; and the latter what belongs to the Spaniards: the ancient divisional line which separated these two parts stretched from the river Pedernales on the south side, to the river Massacre on the north side, at the head of the bay of Manecenille: the Spanish part is reckoned to contain about 90 leagues, in its extreme length from east to west, and about 60 leagues in its greatest breadth, having a surface of about 3200 square leagues; of this surface, nearly 400 square leagues are mountainous; but these mountains are much more capable of cultivation than those in the Haitian division; the soil being little inferior in point of fertility to that of the valleys. The division of Haiti extends 400 miles in length and 140 in breadth; it contains 2,500,000 acres, of which 1,500,000 were in high cultivation before the commencement of the French revolution in 1789: it is for the most part mountainous, but fertile, and full of woods, and mines of silver and iron.

The climate of the whole island is very hot, but the effect of the heat is considerably moderated by the winds and frequent heavy falls of rain; these, however, render it so very damp, that most things become putrescent in a very short space of time. In the plains, in the Spanish part, the heat is nearly uniform, sometimes rising as high as 99°; but as the mountains are approached, it gradually subsides; on them, it rarely rises above 72° or 77°; and during the night, the temperature is so cool as to render covering necessary; on some of the highest mountains, as those of Cibao, Llille, and Holte, the former of which is estimated at about 6000 feet above the level of the sea, a fire is frequently requisite. In the central part of the island, the plains of Banian border on the more elevated districts of St John and St Thomas: the western former, the degree of heat is so perceptibly greater, as according to Walton, to cause a diminutive size in the inhabitants, compared with those of St John's and St Thomas. The valley of Costanza, which is divided from the district of St John's by a high ridge of mountains, and is closed in like an amphitheatre by surrounding hills, has a still cooler climate: meat there can be preserved five or six days untainted: hoar frost is frequently seen in the evening, and a fire is generally necessary. The climate may be divided into two seasons; the wet and dry: the heaviest rains fall in May and June; the prevalent winds are from the east, which cool the air; a south or west wind renders it sultry. In January north winds are not uncommon; they occasion a cold dryness in the atmosphere. Sea and land winds are common; about 10 o'clock in the morning, the regular easterly breeze sets in; towards the evening, the land wind springs up, but it does not reach to a great distance from the shores. Hurricanes are seldom experienced; when they occur, they are preceded by a close sultriness of the atmosphere; earthquakes are not now nearly so frequent as formerly. In the southern part of the island, violent gales of wind are not uncommon, but they are not attended with such dreadful consequences as the hurricanes in the windward islands. The principal cause of the unhealthiness of the climate of St Domingo seems to be the alternation of violent heats and heavy rains; and as this alternation prevails in a greater degree, and more frequently on the sea shore, it is more unhealthy than the interior parts of the island. The moisture of the climate has been already noticed; and from this cause, as well as from the attacks of small insects, while the French held possession of the west end of the island, copies of all the transactions and records were transmitted to Paris, to secure them from the destruction of the colonial climate. Walton remarks, that even the texture of the paper is destroyed.

The soil in general is a rich clay; in some places mixed with light gravel, lying on a substratum of rock. It is remarked that the upper soil is deep, in proportion as it is less humid, and easily broken. In this kind of soil, vegetable remains are often found. The direction of the hills in St Domingo is similar to that on the other islands, being parallel with the bearing of the island; their summits form a regular curve; there are two great chains of mountains, which stretch from east to west; from these numerous spurs branch out. Cibao, one of the loftiest, has been already stated to be about 6000 feet above the level of the sea. The Valleys are very numerous, and in general extensive and fertile. The valley of La Vega Real is one of the largest and finest in the island; its length is computed at 80 leagues, and its breadth at 10, and in some places at 15. To the east of the city of St Domingo, are those immense plains, which are emphatically called Los Llanos; they are perfectly level; with no trees upon them, except a few small shrubs on the margin of the springs or pools of water. These plains are said to occupy nearly a sixth part of the island, stretching almost to the east end, a distance of more than 90 miles, while their breadth is about 30 miles. The River Ozama is watered by several rivers, the principal of which are Ozama, Haina, Nigu, Villegas, Norsac, Ocoa, and Yane; they take their rise in the mountains, and in general descend towards the west. There are, however, some which flow to the north and east; but these are not so large as the others. Ozama falls into the sea at the city of St Domingo, where it is as wide as the Thames at Chelsea; about a league above the city it is joined by the Isabella. In rainy seasons, the current is very rapid and strong; and the colour of
the water muddy for several miles; over the bar there is from 14 to 15 feet depth of water. This river is a great convenience to the city, in conveying down provisions and produce from the interior. There is no bridge over it; but the cattle are swan across, even when the current is very powerful, with wonderful ease and dexterity. About 3 leagues to the west of the city of St Domingo, the Haina flows; it takes its rise at the foot of a beautiful ridge of mountains, which terminate the prospect from the city; its course is very winding through the valleys; it falls into a bay of the same name; it is navigable at some distance up, but not near its exit into the bay, owing to an irregular bar of sand. The river Nigua rises near the Haina; its course is so very serpentine, that in travelling two miles, it is necessary to cross it five times. The length of its whole course is nine leagues; in its progress it receives several smaller streams; in the dry season it is very low, and except when greatly swelled by the rains, is easily and safely forded; much wood is floated down it. The river Yane flows through an extent of nearly 200 miles, and waters the rich plains of La Vega Real, Cotuy, &c.: it receives upwards of 40 smaller streams, and falls into the great bay of Samana. This bay, in point of situation, extent, and communication with the interior of the country, is one of the most important in the West Indies. From a sugar loaf hill, we have Cape Raphael, which forms the south side of this bay; to the opposite side is a distance of 18 miles, protected by rocks and sands, yet leaving a safe and deep channel: it is 60 miles long, and bounded on every side by a fertile country. This most important bay seems to have been much neglected by the Spaniards, but when the Spanish division was ceded to France, that government ordered it to be surveyed in a very exact and particular manner; even before the cession of the Spanish division, they attempted to gain possession of a tract of land, cut off by a line drawn 12 leagues inland of Degason to Cape Raphael, which would have included the bay of Samana. This attempt they made in consequence of their justly regarding this bay as the key to the Mexican gulf, from its windward and commanding situation; they also looked forward, by obtaining it, to the possession of the river Yane, the sea ports to the north, the rich mines of Cibao, and the finest tobacco lands in the island: in this project they were defeated, but when the whole of the Spanish divisions were ceded, the French officers used all their endeavours and interest to have land ceded to them near the bay of Samana. There are several other bays, some of which require to be noticed: Neyba bay, into which a river of the same name enters, might be made large and commodious for shipping, if the various channels, through which the river flows into it, were formed into one; at present the depth of water is small, and the pilots, from the number and frequent shifting of the channels, are often at a loss for the proper navigation. The entrance of Ocoa bay, which is denominated from a river of the same name, is two leagues across; and it increases gradually within nearly to six leagues. Its shape resembles the Greek omega; its shores are clear, and their elevation makes it a good place for shelter. On the east side of the bay is the harbour of Culdera. Here Spanish ships, which draw too much water to cross the bar, lie to complete their loading, moored to the trees with a rafter ashore. A great part of the coast of the island is rocky and dangerous, affording insecure anchorage or shelter from storms.

Formerly there appear to have been considerable mines of gold, silver, copper, and iron; but the mines of the two former metals have long been closed by order of the Spanish government, probably from a wish not to interfere with the mines of the American continent. About eight leagues from the city of St Domingo, the mines, known by the name of Buena Ventura, were situated; from one of these mines, called Cibao, a piece of gold, weighing 200 ounces, was obtained; when it was assayed, it was ascertained that the metal was so very pure that 20 ounces would not be lost in the melting; it was unfortunately lost in its passage to Europe. Even at this time, in the neighbourhood of these mines, the inhabitants, after heavy rains, find among the sands of the rivulet, Santa Rosa, small particles of gold, sometimes to the amount of an ounce a-day. In the centre of the island, are also remains and vestiges of extensive gold mines; these were the first that were wrought, and at one time were very productive. In the southern part of the island are the mines of Guaba, Rubia, and Baoruco; gold is still found here in small quantities, with little or no trouble or difficulty, especially by the Maroons, who inhabit this part of the island. On the borders of the small streams called Obispo and Piedras, there is a rich silver mine; and not far from the capital, an excellent vein of this metal has been wrought. On a ridge called Maymon, near the centre of the island, there is a copper mine; and within a very few leagues of the city of St Domingo, there are two valuable mines of iron. In the year 1645, quicksilver was found at the source of the river Yaque; and it has also been met with near the gold mines of Cibao. Emeralds have been dug not far from the copper mine already mentioned; the leadstone is found in several places; and also jasper, porphyry, alabaster, and agates. Besides these, Walton mentions a mine of antimony, which yields pieces of six and eight pounds, and what he calls mineral copperas. The mineral treasures of this island are, however, very imperfectly known, though, from the accounts given by Herrera, and other Spanish authors, they seem to have been the object of very scientific and accurate investigation; according to him, the mines of La Vega and Buena Ventura alone, formerly exported upwards of 460,000 marks of gold. No mineral waters have been discovered in St Domingo, except those which suddenly burst forth from the mountains of Viagama, in consequence of the dreadful shocks of earthquakes, which were felt in this part of the island, in the year 1751: they are strongly impregnated with sulphur. One of the most singular natural curiosities in the island is the lake of Henriquello, or the Little Henry; it lies near the south part, of the French line of demarcation, forming one side of the beautiful valley of Neyba. This lake is about 22 leagues in circumference; the water is deep, clear, and salt, though its nearest margin is eight leagues distant from the sea, from which it is divided by several considerable mountains; and what is still more remarkable, there are regular tides in it, at the same time that they take place in the neighbouring ocean; lizards, alligators, and even the shark, seal, porpoise, and other sea fish, are found in it. Near the middle is an island about two leagues long, and a league wide, in which is a spring of fresh water, stocked with goats, and thence called Cabrito island.

The vegetable productions of St Domingo are exceedingly numerous, and some of them are very curious and valuable. The mahogany tree, which is at present the staple export commodity of the country, is
very abundant; by the old Spanish laws it was deemed unlawful to cut it; such as grow in a dry barren soil is harder, more close in the grain, and more finely variegated, than what grows in low damp situations. Walton says, that he has seen a canoe formed out of the trunk of the mahogany tree, capable of holding 100 men. The oak, though of the same species as that of Europe, differs considerably in its appearance; it is used for buildings, and frequently furnishes beams from 60 to 70 feet long. The *haena* is a tree very similar to the oak, but its wood is still more durable. The *chicle* affords a most beautifully veined wood; but it is dangerous to work at it in contact with the poisonous juice which it contains. There are several woods for dyeing, but none of them have been tried, or even accurately described, except the *fusíce*; there is another tree, somewhat resembling the *fusíce*, which affords a beautiful dye of a more greenish yellow. Two kinds of lignum viwe grow along the coast; the *quebrach hacho* (break axe) is of the same species; it has the peculirity of becoming nearly as hard as stone, when stuck in damp ground. The Spaniards generally build their vessels of a tree called the *capan*, which, however, seems better suited for sheathing ships. The pine is abundant, but in consequence of its being very liable to be attacked by the wood ant, it is seldom employed. Brazil wood is found on many parts of the coast, but hitherto it is not much attended to. The satin wood of St Domingo is heavier than that which grows in the East Indies; but it takes a much better polish, and does not require to be varnished: the value of it is nearly equal to that of mahogany. Of all the vegetable productions of the island, the *seiba*, or cotton tree, is the largest; of it the lightest and most capacious canoes are made; it receives its name from a down, which it affords, resembling cotton, but of a shorter staple, not unlike the down of the black poplar; with this substance the Spaniards stuff their beds; and some successful attempts have been made to form hats of it. The juice of the fruit of the *jagua* is as clear as water, yet it gives a stain to linen of a dark black colour, which is very permanent; on account of this quality, it has been used for dyeing; it is also employed in baths as an astrigent. Of the wood of this tree, which is firm, straight, and supple, the natives make their best lances. The fruit of the *genopa*, or sand box tree, is more singular than valuable; "it resembles a perfect sand box, of a round form, with little raised regular divisions, in shape such as we give a cake by means of a pattcy pan, which terminates in small fibres in the centre, through which the sand filters, and drops into the inside. The traveller is sometimes startled in riding under them, by a noise resembling the discharge of a pistol; but finds it is the fruit that has exploded, and shivered in a thousand pieces;" the sap is of a very acrid nature, and if it falls into the eye produces excruciating pain, and even in some cases blindness. Green and black ebony, granadillo, and the palmetto, or mountain cabbage, are very common; the annual growth of the last is marked by a dark circle, at about the regular distance of three inches. The roofs of the houses are covered with the envelope of the cabbage, which fails periodically every month to the ground; it is about three feet long and one broad. The juice of the dwarf palmetto is called *alegro cogate*, or **livener of the brain**, by the natives, from the property which it is said to possess of raising depressed spirits, when applied to the temples and back of the neck. The sugar cane, cotton, and coffee plants, flourish remarkably well in St Domingo. The sugar would be of an excellent quality, were it properly and carefully manufactured. The quality of the coffee is remarkably good, little inferior, it is said, to that of Mocha; each tree, if properly attended to, will produce, on an average, a pound weight. Cotton, of an excellent quality, grows naturally, even in the stony soil, and in the crevices of the rocks. Indigo seems at one time to have been greatly cultivated; but at present it is in a great measure neglected. The kernel of the cocoa nut of St Domingo is more acidulated than that of Venezuela and the Canarrieas; and the chocolate made from it is esteemed to possess a higher flavour. The plaintain, banana, or fig plantain, calabash, and cashew nut, are abundant. Vanilla is indigenous in the woods; but though a useful and valuable plant, no attention has been paid to its culture or commerce in this island. In the country round the bay of Sanata, the malagueta, or paradise plant, grows in great abundance; as it is a native of the East Indies, it is thought to have been introduced by Columbus, who frequented this bay more than most other parts of the island; the Spaniards use it to season their most favourite dishes. The tobacco of St Domingo, according to Valverde, has a larger leaf than on any other part of the continent of America; and in quality is equal to that of Cuba or the Havannas; it is found in most parts of the island, but it is cultivated to the greatest extent, and with the most care, in the districts of La Vega and Santiago: by the manufacturers of Seville it is in great esteem, and for segars, it is preferred by them to all other kinds. Two crops of rice are annually gathered; but this crop is not so abundant or productive in St Domingo as in Porto Rico. The natives manufacture hammocks of the fibres of the leaf of the *peta*, a species of abaca. This tree grows in every part of the island, but particularly in Santiago. The flowers are exceedingly numerous, and some of them particularly distinguished by the brilliancy of their colours, and the fragrance of their smell; the most singular, or the most valuable of the fruits, are the vegetable narrow, melon, guava, pine apple, mango, &c.

Of the four species of quadrupeds which were found indigenous on the island on its first discovery, the *hutia*, or agouti cat, only remains. It is of a grey colour, and in form something between the squirrel and the rabbit: it burrows in hollow trees; but when pursued, takes refuge in the depth of the forests. Though assisted by its tail in climbing the trees, or in springing from one tree to another, it is not nearly so nimble as the squirrel: even this animal is nearly extinct in Domingo, being found only in Santiago. All the other quadrupeds were introduced by the Europeans, and they have increased greatly, especially cattle, hogs, sheep, goats, horses, mules, and asses. There are graziers in the district of Seibo, who keep upwards of 12,000 head of cattle, which they sell in herds at six and eight dollars per head; and when the census of the Spanish division was taken in 1780, 200,000 head of cattle were returned; so that the number then, making allowance for those which did not pay the tribute, could not be fewer than 250,000. It is probable, however, that, in consequence of the unsettled state of the island since that time, the number is not now nearly so great. According to Walton, the whole of the cattle in the island do not exceed 300,000; the horses, mules, and asses, he estimates at 150,000. The island abounds in birds, curious for their plumage or song: among these are the flamingo, wild peacock, Jamaica nightingale or mocking-bird, and the banana bird. Among the amphibians and fishes, are the turtle, caro-
The manufactures and commerce of the Spanish division are very much neglected. There are but 22 sugar manufactories of any consequence; and the negroes employed in them do not exceed 600. Of these manufactories, six produce syrup, and some sugar; but the others, which are called \textit{trypicles}, where animals are employed to turn the mills, which press the canes, make nothing but syrup. All the produce is consumed in the colony, except small quantities, which are sometimes sent to Porto Rico or Old Spain. The number of men organized as a militia, amounts to about 8000; but if the militia laws were carried regularly and fully into effect, the number would be raised to 12,000.

In 1726, the French division contained 100,000 negro slaves, and 30,000 white colonists. At that time its greatest commerce was tobacco, with which, from 60 to 100 vessels were laden annually. Immediately before the commencement of the Revolution, according to Mr. Edwards, the population amounted to 30,831 whites, and about 480,000 negro slaves, the mulattoes or free people of colour being estimated at 34,000, but according to Alcedo, at this period the population consisted of 42,000 white people, 44,000 free people of colour, and 600,000 slaves. The number of deaths during 1789, according to the bills of mortality, was 7121; the number of births the same year, 4232. This great excess of deaths is accounted for by the fact, that, in the two years immediately preceding, 60,000 negroes had been imported into the colony. The merchandise landed in the various ports of France from the island of St Domingo in the year 1789 was as follows: 84,617,328 pounds of coffee, 217,463 casks of sugar, white and brown, 5836 casks of molasses, 3,257,610 pounds of indigo, 1,556,017 pounds of cocoa, 11,317,226 pounds of cotton wool, 1514 scorns of Spanish cochineal, 6914 scorns of logwood, fustic, Nicaragua wood, and lignum vitae, 1685 tons of mahogany, 4018 bags of black pepper, 2426 bags of ginger, 380 casks of gunnison and other gums, 248 boxes of aloes, cassis, and... Chicle, 26,948 h des tanned, 114,659 hides in the hair; from the Spaniards, 4107 pounds of tortoise shell, 27,812 barrels of syrup, 1946 boxes of sweetmeats, 1478 scorns of Jesuits bark, 2,617,493 dollars, 57,518 ounces of gold in grains from the Spaniards; the total value of these products was estimated at L.6,094,230. According to Mr Edwards, the average exports before the revolution consisted of 58,642,214 pounds of clayed sugar, 86,549,829 pounds of Muscovado, 71,663,187 pounds of coffee, 6,698,858 pounds of cotton, 951,607 hogheads of indigo, 23,061 hogheads of molasses, 2600 hogheads of an inferior kind of rum called \textit{tafia}, 6500 raw hides, and 7700 tanned ones, the value of which exports was equal to L.4,765,129. In the same year, 710 vessels navigated by 18,460 seamen, and admeasuring 213,540 tons, sailed from Bordeaux, Nantes, Marseilles, and other ports in France, for St Domingo; their cargoes consisted of a great variety of articles, amongst which were French linens, car-

Exports to
France.

Exports before the
revolution.

Imports from
France to
St Domingo in
1789, amounted to
L.4,125,610. At
this time, a very considerable trade was carried on
between the French colony and the Spanish settlements
in the island, in the other islands, and on the main,
the Spanish ships which arrived amounted to 283,
most of which brought dollars and other articles to
the amount of L.2,450,115, to purchase European goods,
slaves, &c. Most part of this trade was contraband.
The import of slaves into French Domingo in 1789 was not inferior to what it had been in the preceding years; the numbers being 35,263. There were brought in 119 large ships, navigated by 415 seamen. From the Spanish part of the island, there was, on an average, annually smuggled into the French division 25,000 horned cattle, and 2000 mules and horses; but as the value of these goods was not nearly equal to the value of the negroes, &c., which the Spaniards obtained, it is supposed that nearly $300,000 in cash were annually sent to make up the balance. There was also a considerable trade between the United States and French St Domingo. In 1789, 684 vessels from America, on an average measuring 70 tons, arrived in the French ports of St Domingo. Their cargoes consisted principally of provisions, East India goods, English manufactures, and lumber; and they took back the various productions of the island. The annual returns were estimated at eight and nine hundred thousand pounds.

Of the commerce of this island subsequently to this period, few authentic particulars are known. From the year 1804 to 1808, according to Mr Walton, "75 vessels, on an average, annually visited her ports with small cargoes, in all amounting to the value of about L150,000 sterling, which they laid out chiefly in wood." Silesian and English goods were imported by the Danes, and provisions, wine, and lumber by the Americans. The author last quoted is of opinion, that this island is capable of furnishing annually 10,000 logs of mahogany, each containing on an average 300 feet, 500 tons of lignum vitae, 500 tons of hickory, 400 tons of logwood, nearly 1,000,000 pounds of coffee, 10,000 hides, besides cotton, indigo, &c.; and he reckons the annual amount of duties which St Domingo productions pay in England in war time, at the sum of L45,000. By a commercial treaty between Major General Carmichael and the governor of the Spanish part of the island, executed in August 1809, all vessels bearing the British flag, are to pay the same duties as Spanish vessels, by which regulation, the import duties will not exceed 5 per cent. and the export duties 6 per cent.

The Spaniards held undisturbed possession of the whole island of St Domingo for upwards of 120 years. About the middle of the 16th century, a number of French Buccaneers, most of them natives of Normandy, settled on Tortuga, a small island lying to the north of St Domingo. From this place they made constant incursions against the Spanish settlements, till at last, by the treaty of Ryswick, that part of the island in which they had established themselves, was ceded to the French king, who had acknowledged them as his subjects, and taken them under his protection. No other event of importance occurred in the history of the island, except the attempt made upon it by Admiral Pen, which has been already noticed, and a dreadful mortality, occasioned by the measles and small-pox, in the year 1666, which is still remembered by the appellation of La Tragedia de los seis, the tragedy of the sixes. When the French revolution began to assume its wild and violent character, the immediate and unprepared freedom of the slaves in their West India islands was one of its first measures. The consequences in St Domingo were most dreadful; the slaves rose and massacred the whites, and in a very short time, the French division was rendered desolate and barbarous, and all the white families who had lived in their power emigrated. The English wished to take advantage of these disturbances; but after the loss of an immense number of their troops, principally by the dreadful unhealthiness of the climate, they were obliged to evacuate it. In 1795, the Spanish government ceased to protect the island, and on the 18th of the 9th of the year 1801, when the black general Toussaint, who commanded the troops of that nation, fixed his brother Paul in the command of it. But the real power of the French in the island was very trifling; and to restore this power, one of the first acts of Bonaparte, after the peace of Amiens, was to send out a very large army under the command of General Le Clerc. This expedition was, in the highest degree, disgraceful and disastrous. By an act of the greatest duplicity, Toussaint indeed was removed out of the way; but the French troops, after being repeatedly defeated, and losing an immense number of men, were compelled to evacuate the island, with the exception of a very small force which withdrew to the city of Domingo. The blacks now formed themselves into a regular government, and their chief Dessalines assumed the supreme authority. He was of a most ferocious disposition; and having exercised his cruelty upon his subjects, as well as upon such whites as fell into his power, he was put to death by the former. The empire of Haiti, (for so it was denominated) was dispossessed by many chiefs after the death of Dessalines. The most celebrated and successful were Petion and Christophe; the former held possession of the southern part of the island, and Christophe of the north. Obstinate and bloody wars have taken place between them; but the population under Christophe is the most numerous. His troops amount to 10,000 men, and is possessed of superior talents and good decision of character. At the commencement of the Spanish revolution, hostilities broke out between the Spanish inhabitants and the French troops who were in that division of the island. The latter being defeated, took refuge in the city of St Domingo, but they were obliged to capitulate and evacuate the island, in consequence of General Carmichael, with a considerable body of British forces, joining the Spaniards in the summer of 1809. (w. s.)

DOMINGO, St, the capital of the island, is in the division belonging to the Spaniards. It lies in 18° 28' North Latitude, and in 69° 50' West Longitude, on the west bank of the Ozama. It was founded by Columbus in 1494, and received its name either because it arrived in the island on a Sunday, or in honour of his father. It was originally built on the east side of the river, but a great part of it having been destroyed by a violent hurricane in 1502, and this calamity being followed by a pestilential visitation of destructive ants in 1504, it was removed to its present site. The port, though only fit for small vessels, is convenient and safe, and contains a natural basin, in which a great number of vessels may anchor. The form of the city is that of a trapezium of about 340 fathoms on the east side along the river, nearly 500 fathoms on the south side bordering on the sea, and about 1800 fathoms in circumference. The streets are straight and broad, crossing one another at right angles; ten of them run from north to south, and two from east to west. The whole city is surrounded by a rampart 8 feet in diameter, and about 10 feet high; the fortifications, however, are not strong, and is completely commanded by some adjoining heights. The appearance of the town is represented as picturesque, but rather gloomy, by reason of the massive piles of buildings, unadorned with steeples; but the gardens interspersed among the houses relieve this effect, and give it a romantic air. The most ancient buildings are built of a species of marble found in the
DOM

DOMINICA, an island of the West Indies, was discovered by Christopher Columbus, on November 3, 1493, and received from him its name, from the circumstance of its having been discovered on a Sunday.

This island is about 29 miles long, and 16 broad. It is divided into 10 parishes, and contains 186,436 acres of land. It contains many lofty and rugged mountains, separated by tolerably fertile valleys, which are watered by about 30 rivers, and a great number of rivulets. Hot springs are found in various parts of the mountainous country, and there are several unextinguished volcanoes, which often throw out quantities of burning sulphur. In the interior of the island, the soil, which resembles that of Martinique and Guadaloupe, is a light brown mould, formed by the detritus of the mountains; but in the valleys, and towards the coasts, it is a black rich earth, well fitted for raising every article of colonial produce. The principal productions of the island are sugar, coffee, cacao, indigo, and ginger. The number of sugar plantations does not greatly exceed 50, and the annual produce is about 3000 hogheads. The coffee plantations are about 200 in number, and in favourable years raise about three millions of pounds weight of coffee. The cacao, indigo, and ginger, are cultivated only in small quantities.

The following is a statement of the exports from the island, during the year between January 5th 1787, and January 5th 1788:

Total population 16,648

There are still about 20 or 30 families of the aboriginal inhabitants, who are industrious and inoffensive. They are of a clear copper colour, with long sleek black hair, and are short, stout, and well made. They subsist chiefly by fishing, and by shooting with the bow and arrow.

The principal towns in the island are Portsmouth and Roseau, or Charlotte’s town.

At the peace of 1763, Dominica was confirmed in the possession of the English, who had subdued it in 1759. In 1778, it was taken after an obstinate resistance, by the French, under the Marquis de Bouillé, governor of Martinico, and, after continuing in their possession for more than five years, it was restored to England by the peace of 1783.

In 1803, a formidable French squadron made a descent upon the island, and burned the capital, Roseau; but the island was preserved to Great Britain by the skilful management of Sir George Prevost.

The position of Roseau, the capital, according to solar observations, is in West Long. 61° 32' 15", North Lat. 15° 18' 29". (π)

DOMINICAL LETTER. See Chronology, p. 409.

DOMITIAN, one of the Emperors of Rome, and the last of the twelve Caesars, was the second son of Vespasian, and was born at Rome on the 24th of October, A. D. 51. He bore the name of Titus, Flavius, Sabinus Dominianus; and appears to have spent his youth in idleness, indifference, and vice. When his father Vespasian was contesting the empire with Vitellius, he retired with his uncle Sabinus to the Capitol, where he made a narrow escape by concealing himself in an apartment of the temple, and secretly withdrawing to the house of a friend. Upon the death of Vitellius, A. D. 69, when Vespasian was still in Judea, Domitian was proclaimed Cesar at Rome; and continued, during his father’s absence, to bear the chief sway. His first appearances in the senate were modest and prepossessing, and his first acts of government were conciliatory and popular; but he soon abandoned himself to the pursuit of his pleasures, and employed his power only for the gratification of his vicious inclinations. Ambitious at the same time that he was dissolute, he pretended to usurp every kind of authority; and, in one day, bestowed so great a number of offices, both in the city and the provinces, that his father is said to have written in one of his letters, “I thank you for not having yet sent me a successor, and for your kindness in vouchsafing to let me enjoy the empire.” Jealous of the fame which his brother Titus had acquired in the Jewish war, he resolved to take the command against Civilis in Gaul, and had actually reached Lyons with that design; but was persuaded by Mucian, who knew his inexperience in military affairs, to content himself with making a display of his princely power in that city. During his residence in that quarter, he secretly endeavoured to corrupt the fidelity of Cerealis, who then commanded in Gaul, either for the purpose of making war upon his father, or forming a party against his brother; but the general evaded all his proposals, and treated them as nothing more than childish fancies. Disappointed in his plans of revolt, he had resolved to dissemble his ambitious schemes, relinquished all the functions of government, renounced even the natural prerogatives of his rank; and, burying himself in solitude, pretended a great zeal for learning, and particularly applied himself to the composition of verses.

With all this affected fondness for retirement, he made frequent applications for a military command; but his father, well acquainted with his disposition and designs, invariably declined entrusting him with an army. At the death of Vespasian, he manifested a disposition to dispute the succession with his brother Titus; pretended, that it was the will of his father, that they should jointly inherit the empire; and even proceeded so far as secretly to solicit the troops to revolt. But, his courage failing him, or his attempts proving ineffectual, he continued during the reign of Titus without any other title, but that of Cesar, a prince of the Roman youth, except that his brother, who always treated him with civility and kindness, made him his colleague in the consulsip. As soon as Titus expired A. D. 81, Domitian hastened to Rome; and promising to the pretorian guards the usual donation, was immediately saluted emperor, in the 30th year of his age. The commencement of his reign was highly auspicious; and he gained the affections of the people by conduct truly worthy of a great monarch. He was assiduous and impartial in the administration of justice; punished, with the utmost severity, all those judges who were convicted of taking bribes; and kept the magistrates of cities and provinces strictly within the bounds of legal authority. He enacted various useful laws for the reformation of manners, the prevention of libels, the regulation of the theatres, &c. He displayed the greatest munificence in presenting large sums to his officers, in order to raise them above the temptation of accumulating wealth by unwarrantable means; in refusing to accept estates which were left to him by those who had children of their own; in forgiving all debts above five years standing due to the treasury; in augmenting the pay of the soldiers, and completing the public works which had been begun by Titus. Even amidst these more commendable transactions, however, he displayed the most consummate vanity, and puerile ostentation; causing himself to be appointed consul ten years successively, doubling the number of lictors that were carried before him, appearing always in the senate in his triumphal dress, continually proclaiming himself "Imperator," or vicarius general, though his armies were generally sustaining defeats; filling every corner of Rome with triumphal arches in honour of his pretended victories, crowning the temples with statues of himself, which he required to be either of gold or silver, and always of a certain height; and continually amassing himself with the most expensive shows and extravagant entertainments. At a very early period, also, he began to give indications of his cold-blooded cruelty; and it is affirmed by some ancient authors, that even while he was professing the most exalted sentiments of humanity, and proposing to forbid the offering of any living creature in sacrifice, he used daily to retire to his apartment to amuse himself with catching flies, and trans-
fortune, he was suspected, and his anxiety for his safety was increased by the approach of the tyrant, whose bloodthirsty vengeance was naturally excited by the jealousy and dread of the tyrant, was sure to be either put to death, or to be deprived of all honour and command. Of this, a striking instance occurred in the fate of the celebrated Agricola, whose successes in Britain were followed by his recall from that province, his dismissal from all military employment, his subjection to the emperor's daily distrust, and finally, it is suspected, by an unfair death.

His principal amusement consisted in the shows of the amphitheatre, which he conducted with the utmost profligacy of expence, and refinement of cruelty. He procured females to run in the circus, and fight like gladiators. He caused an immense lake to be dug near the Tiber, in which he exhibited sea-fights; and frequently prolonged these diversions through the whole night by the light of the moon or of torches. In order to fill his treasury, when exhausted by these extravagant expences, he had recourse to every kind of rapine, extortion, and infamous confiscations; seizing, upon the slightest pretence, the estates of the wealthier citizens, and reducing to beggary the most opulent families throughout the empire. Nor was he more sparing of the lives than of the fortunes of his subjects; and while he plundered those whose riches he coveted, he cut off others whose virtues he dreaded. He commanded the astrologers to cast the nativities of the most illustrious persons in the city, and put to death all those who were pointed out as destined to attain an empire. He accused the knights and senators of treason upon the most trifling grounds, and either procured them to be condemned by the senate, or commanded them to become their own executioners. In the event of any conspiracy or insurrection, he tortured and butchered whomsoever he pleased, by charging them as accomplices. Many of the most virtuous characters he coolly put to death, for no other reason than because their exemplary lives seemed to reproach his debaucheries, and to demonstrate their disapprobation of his conduct. He is said to have taken an inhuman pleasure in beholding the sufferings which he inflicted; and to have delighted in exciting the terrors of those whom he spared. At an entertainment, as described by Dio Cassius, to which he had invited the principal senators and knights, the guests were conducted into a spacious hall, hung round with black, and lighted only by a few melanichol lamps, so as to discover a range of coffins, upon which were inscribed the names of those who were invited. While they were looking in consternation upon this gloomy spectacle, and momentar­ily expecting the doors which had been bolted, the doors suddenly burst open, and they were surrounded by a crowd of naked figures, whose bodies were painted black, holding naked swords in the one hand, and flaming torches in the other. Having beheld these supposed executioners dancing around them for some time, and been made to experience in imagination all the horrors of a violent death, the doors were again opened, and they were permitted to withdraw.

As some of those whom he sacrificed had professed the philosophy of the Stoics, he banished from Rome and Italy all philosophers and teachers of the liberal arts, and commanded many of their writings to be publicly burned. In the 14th year of his reign, A.D. 95, he proceeded to fill the measure of his crimes by a cruel persecution of the Christians, whom he ordered to be treated in every quarter of the empire as declared enemies of the state; all multitudes of whom were either condemned to banishment, or punished with death. Among the noble sufferers in this proscription, may be mentioned the emperor's own cousin-german, Flavius Clemens, and his wife Flavia Domitilla. The apostle John is understood to have been at the same period banished to the Isle of Patmos, where he wrote the Apocalypse. Long before the commencement of this persecution, Domitian had gone so far in his madness, as to declare himself a god, and to require divine honours to be paid to him. But, with all his pretended divinity and sanguinary precautions, he was perpetually harassed with the apprehension of assassination, which was still further increased by certain prodigies and predictions which preceded his death. Hence he became suspicious of his most intimate friends and nearest relatives; and this distrust of his own family only rendered it the more necessary for them to consult their own safety by hastening his end. It is said, that his wife Domitia, having found a paper which a child had taken from the emperor's pillow, and which contained a list of several persons destined for slaughter, with her own at the head of them, immediately formed a conspiracy against his life with the other devoted objects of his suspicion. As if possessed with a presentiment of his approaching fate, the tyrant became doubly circumspect; and among other precautions, is said to have caused the gallery in which he usually walked to be lined with a polished stone, which reflected objects like a looking glass, that he might readily perceive what was doing on every side of him. On the day of his death, as he was going to bathe before dinner, his chamberlain, Parthenius, introduced to him Stephanus, the steward of the banished Domitia, a man of great strength, who bad undertaken to dispatch the tyrant. Having his arm in a sling, as if it had been hurt, he the more easily concealed a dagger; and while the emperor was attentively reading a memorial which he had presented relating to some alleged conspiracy, he plunged the weapon in his belly. Notwithstanding his wound, Domitian struggled for some time with Stephanus, and even succeeded in throwing him to the ground, when the other conspirators, entering the apartment, speedily dispatched him with many wounds. Some officers of his guard, who were not privy to the plot, alarmed by the noise, hastened to the spot, and put Stephanus to death; but the other conspirators had succeeded in making their escape. Thus perished, in the 43d year of his age, and after a reign of 15 years, the most detestable tyrant that ever oppressed the Roman world. The soldiers, whose pay he had increased, and who had frequently shared his banquets, were the only persons among his subjects who regretted his death, and wished to take vengeance upon his murderers. The senators, on the contrary, publicly expressed their joy, and loaded his memory with the bitterest invectives. They ordered all the pictures, statues, and other representations of him, to
DON, the Tanais of the ancients, and the Tuna of the Tartars, is one of the largest rivers in Europe, and the second in magnitude of those which discharge themselves into the Sea of Azof. It rises in the Ivanofskoy Lake, not far from Tula, in the government of Rezan; and after watering a considerable extent of country, it divides into three branches at the town of Tscherschkoy, and discharges itself into the Sea of Azof, where it is so shallow that only flat-bottomed vessels can pass into the sea. The course of this river, exclusive of its windings, is about 1000 vers. It flows in general through a flat country, covered with immense forests of pines and oaks. Its bed is commonly sand, marl, and lime.

In one part of its course, the Don approaches so near to the Volga, that Peter 1. was extremely anxious to form a junction between these two rivers. He himself discovered two practicable tracks. One of these was from the Lower Volga, by uniting the rivulets Kami-shinka and Ilgafa with a canal of four vers. This plan was actually begun, but was abandoned from an insufficiency of water. The reservoirs, which were intended to have been placed at the sources of the Kami-shinka, were scarcely capable of supplying the common stream of the river. The other plan was to unite the source of the Don 25 vers. from the town of Chepishan, with the rivulet Kala, which falls into the Oupa, one of the principal branches of the Oka, which runs into the Volga. This plan was likewise begun, and a considerable part of it carried into effect. Twenty-four sluices of limestone were built, and the canal cut through the extent of the vale of Bobriky, corresponding to the depth of the bed of the Don; but it was abandoned from a supposed want of water.

The rivers which fall into the Don are the Danets, which rises a little above the town of Belgorod, and is generally navigable, particularly in spring, receiving the rivers Eyedor, Koren, and Orkole, which are small and little frequented; the Voronege, which is navigable only in spring; the Bolutzor; the Derkul; the Kalitva; the Somsa, which is generally navigable, and receives the Ostrogosa; and the Choper, which rises from a morass in the province of Penza, and has a course of 360 vers., through a fruitful country, abounding in corn, wood, and pasture. The Choper is navigable through the district of Choperskoy, particularly in spring, and receives the rivers Verona, Kolitkey, Gamala, Milkarey, Arkadak, Karay, Serloba, Ilgafa, and the Medvitsa. See Tooko's View of the Russian Empire; and Clarke's Travels, vol. i. passim. (x)

DONAGHADEE, a maritime and port town of Ireland, in the county of Down, and province of Ulster, situated upon that part of the Irish Channel which separates Scotland from Ireland. The town consists of two principal streets. One of these is open and exposed to the sea; and the other, situated behind the first, is well roamed. The communication between Scotland and Ireland is from Donaghadee to Portpatrick in Scotland, the distance between which is about 25 miles. The quay is formed in the shape of a crescent, and consists of large stones; without any cement. It is 128 yards long, and 22 feet broad, and has a breast wall of the same stones about 6 feet broad. Distance from Dublin 914 miles, and 15 from Belfast. (f)

DONATIA, a genus of plants of the class Triandria, and order Trigynia. See Botany, p. 110.

DONAUHEBENGEN. See Danube.

DONAX. See Convolvulus.

DONCASTER, a large and beautiful market town of England, in the West Riding of Yorkshire, and on the south division of the Wapentake of Strafforth and Tickhill. It is pleasantly situated on the south side of the river Don, on a narrow tongue of land bounded by the Don on the north, and a range of fens or marshes, called Potteric Car on the south. The principal street, which in different parts of its length has the name of Hall-gate, High-street, French-gate, and Marsh-gate, forms one line, and is part of the great north road from London to Edinburgh. It is nearly a mile in length from the Hall Cross on the south-east, to the Mill Bridge on the north-west. The street, which runs from the north-east extremity of the town to the west end of St Sepulchre's gate, in the direction of the road to Rotherham and Sheffield, is above half a mile long. Several new streets have recently been laid out on the east side of St Sepulchre's gate, and many elegant houses are already erected.

The parish church of St George is situated near the river, on the site of an ancient castle, and appears to have been built at different periods. A stone bearing the date of 1071 was lately taken out of the wall at the east end. The church is 154 feet long, 78 feet high, and 68 feet broad. It has eight bells, an excellent organ, and a good library. The tower, which is 141 feet high, appears to have been built in the reign of Henry III. There is also in Doncaster a number of other places of worship, viz. a Presbyterian chapel, the Methodist chapel, an elegant chapel belonging to the Independents, a meeting-house for the Society of Friends, and another for the followers of Joanna Southcote.

The charitable institutions are, a public dispensary, erected in 1792, and supported by voluntary contributions; St Thomas's hospital, established in the 50th year of Queen Elizabeth, for six decayed housekeepers of good character; a workhouse for the employment of the poor; a school of industry; and several Sunday schools.

The mansion-house is a very magnificent building. It is in the centre of the town, and was erected in 1744, and enlarged and thoroughly repaired in 1800.

The town-hall, where public business is transacted, was repaired in 1782; and affords room in its lower apartments for the free grammar-school. An English school has also been established by the corporation, and there is likewise a good theatre.

Several unsuccessful attempts have been made to establish manufactures in this place. The only one which is at present carried on, is one of machines for cutting straw and splitting beans, and invented by Mr Thomas Pasmore. It is carried on under the firm of Pasmore, Jenkinson, Pearson, & Co. and has met with great success.

The markets of Doncaster are well supplied. The sheds, built in 1756, are covered with a slated roof, and supported by 24 columns. The butter cross is a building of an octagonal form, supported by pillars. The fish market, the vegetable market, and the pottery ware market, are held in a large square called the Market. The corn market, where a great quantity of
grain is sold, is held in a spacious area farther to the north. The two annual fairs are kept on the 5th of April and the 5th of August, for horned cattle, sheep, horses, and coarse woollen cloth.

The corporation of Doncaster possesses an annual revenue of L.7000, which has always been munificently expended, for promoting the prosperity of the town, and the comfort of its inhabitants. The corporation consists of a mayor, a recorder, a town-clerk, twelve aldermen, and 24 common councillors.

As Doncaster contains a great number of opulent families, and of genteel families of small fortune who have selected it as a desirable and cheap place of residence, the means of education are numerous. There are no fewer than eleven large boarding-schools for youth of both sexes.

The race-ground of Doncaster, and the great stand for the accommodation of the company, are the finest in the kingdom. The race-ground is enclosed by a beautiful railing; and the races are among the finest and the best attended in the country.

Doncaster was a Roman station, and is the Dumum of Antoninus, the Caesar-dunum of Nennius, the Dona-cereum of the Saxons, and the Doncaster of the Scots. For a particular account of its history and antiquities, we must refer the reader to Miller's History of Doncaster.

The following is an abstract of the population return for the borough of Doncaster, for 1811.

Number of inhabited houses. 1438
Number of families that occupy them. 1557
Houses building. 28
Uninhabited houses. 42
Families employed in agriculture. 173
Do. in trade, manufactures, &c. 833
Do. not comprised in these classes. 551
Number of males. 3110
Number of females. 3825
Total population in 1811. 6935
Do. in 1801. 5697
Increase since 1801. 1238

See Miller's History of Doncaster and its Vicinity, Doncaster, 1804, which is a very valuable work; and Bigland's Beauties of England and Wales, vol. xi. p. 519, &c. (\*)

DONDRA HEAD, or DONDRE HEAD, called by the natives Dewallum, Dewander Head, or Devi-noor, is the most southern extremity of the Island of Ceylon. It is a low point, having a grove of tall cocoa nut trees on its extremity. The populous village of Dondra, in its neighbourhood, was at one time a place of great note, and was much frequented on account of a magnificent Hindoo temple in its vicinity, which is now in ruins. The fort of Matura was built by the Portuguese and Dutch from the stones of that edifice. Another temple much resorted to by the Cingalese, still exists. It is about 12 feet high, and 150 in circuit. A bell-shaped stone rises from the centre, so as to make the whole height about 30 feet. A full account of this edifice will be found in Perceval's Account of Ceylon, p. 155.

Dondra Head is situated in 80° 43' of East Long. and 5° 53' of North Lat. (\*)

DONEGAL, a county of Ireland, and the largest in the province of Ulster. It formerly went under the name of Tyrconnell; and was a separate principality, with powerful chieftains over it, so late as the time of Queen Elizabeth. It is situated on the northwest extremity of the island; and is bounded by Londonderry and Tyrone on the east, by Fermanagh on the south, and by the Atlantic Ocean on the north and west. Its general aspect is bleak and forbidding. Though its shores are finely indented by the sea, though it has many rivers, and much hilly ground, yet it presents little either of grand or of beautiful scenery. With the exception of a few spots, in which taste and enterprise have combined to supply the want of local advantages, or to improve those which already existed, there is nothing to gratify a traveller's eye. Nature has not been liberal, and art has been almost wholly idle. The most attractive scenes and prospects are those at Brownhall, near Ballyshannon; Donegal bay, and the bridge of Inver in its neighbourhood; Woodhill; the approach to Major Nesbit's of Glentis; Hornhead, where there is a remarkable cavern; the Ards, the seat of Mr Stewart; Mount Alt, from the summit of which the views are truly magnificent; Ramelton, near which is the residence of Sir James Stewart; the Bishop of Derry's seat at Faun, in the barony of Finisheen, from which the views of Lough Swilly are exceedingly grand.

This county, with respect to soil, is, upon the whole, remarkably unfavourable for the cultivation of every kind. It is cold, rainy, and tempestuous.

From the nature of the soil and the climate, agriculture cannot be supposed to be in a flourishing state. And when, besides these untoward circumstances, it is recollected that the farmers are poor and unskilful, that they have no proper stimulus to exertion, and no encouragement from the proprietors, almost all of whom are non-resident, it is easy to believe that the husbandry of Donegal is wretched and unproductive. To this general remark there are some pleasing exceptions; and in certain quarters, for instance in the neighbourhood of Raphoe, great improvements have lately taken place. Hills, and the steep sides of mountains, which formerly produced nothing, are beginning to be covered with oats, potatoes, and flax. The most improved part of the country is the part adjoining Tyrone, where there is a district about 17 miles long and nine miles broad, with a good soil under tolerable management, and yielding crops proportionate to these advantages. Still, however, the great proportion of the land is either not cultivated at all, or cultivated in the most slovenly way.-Very little wheat is grown in this country. Some peas are to be seen; but the great quantity of rain that falls renders this a precarious and unprofitable crop. Barley is cultivated all along the coast, and forms a regular branch in the rotation. Oats, potatoes, and flax, also are raised to a considerable extent. Clover is almost unknown. The fiorin grass is approved of by some, but not much used.

In the following Table, the reader will see the average of the seed and produce of different crops:
Donegal.

\[
\begin{array}{ccc}
\text{|
| Crop | Seed used per En. Acre | Produce per English Acre | Proportion between soil and produce.}
\hline
\text{Wheat} | 140 | 1,750 & 1 to 12.5 \\
\text{Barley} | 210 | 2,100 & 1 to 10 \\
\text{Oats} | 280 | 2,240 & 1 to 8 \\
\text{Potatoes} | 1550 | 10,320 & 1 to 11.5 \\
\text{Flax} | 17 | 8 cwt. & 1 to 457 cwt. \\
\end{array}
\]

In 1809, there were supposed to be sown about 6600 acres of flax, from the produce of which there would be saved 7500 bushels of flax seed; and of that, bounty was allowed on 5600 bushels, bringing L. 1400 of bounty, at five shillings per bushel.

The manures used in this county are various. Lime, and limestone gravel, though found in great abundance, are seldom or never employed. Sea sand is made use of. Sea-weed is laid on the ground in which potatoes are to be planted; but it makes them watery and unfit for the table. Dung, of course, is the principal manure. It is not collected, however, with much care, or applied with sufficient skill.

The practice of fencing has made little progress; the chief fences, even in the most cultivated districts, being only grass banks thrown up to mark the boundaries. It is necessary, therefore, for the cattle and sheep to be herded whenever there is any corn; and as soon as the corn is harvested, they roam at large through all the fields.

Tillage is done in many places with the spade. This implement is thought to be best in preparing the ground for potatoes. Potatoes are sometimes planted by means of a dibble or stevens. Besides the common spade, they also make use of the long Leitrim lays, which resembles a tool employed by the land drainers in England. The two horse Irish plough is the plough in ordinary use.

Cattle, sheep, &c.

There are not many cattle produced in this county. Heifers and young bullocks, when 2 or 3 years old, are brought from the mountains, and taken to the Scotch and English markets for feeding. Very few are fattened, even in the most fertile districts. Indeed the pasture is in general very indifferent. And the attention of the people is chiefly occupied with the breeding of milk cows, tillage, and manufactures. There are scarcely any liberties. The sheep are few in number, and extremely bad in kind. On the mountains there are some, which are represented to be as fleet as greyhounds. In the barony of Inishoen, as soon as the corn is carried home, the sheep of the small tenants herd together, and rove about indiscriminately in search of food. There are multitudes of goats here, as in most other parts of Ireland. Rabbits also are found in considerable abundance. On the northern shore there is a warren of some extent, bringing an annual revenue to its proprietor of between five and six hundred pounds.

The average prices of labour, &c. were estimated in 1811 to be as follow: A man the year round L.8, 11s.; a woman, do. L.3, 15s. 6d.; carpenter per day, 2s. 7d.; mason, do. 2s. 10d.; plaster, do. 3s. 3d.; quarryman, do. 2s. 1d.; thresher, do. 1s. 3d.; mason per perch 3s. 5d.; plaster per square 6s. 3d.; bricklayer per perch, 1s. 6d.; car and horse per day 2s. 6d.; saddle horse, do. 3s. 9d.; plough, do. 5s.; grazing a cow per week 1s. 9d.; ditto horse, do. 8s. 10d.; shewing a horse 3s. 2d.; labour in harvest of hay or corn per day 1s.

74d.; mowing grass per acre 5s. 6d.; day labour of children 5d.; fencing per perch 1s. 5d.; blacksmith's work per day 2s. 6d.; ditto per lb. 7d.; line per barrel 1s. 4d.; bricks per thousand L.1, 6s. 4d.; a car mounted L.3, 2s. 9d.; hay per ton L.2, 10s. 10d.; potatoes per stone 3d.; wheat per barrel L.2, 5s. 6d.; prices of articles of food.

The fuel commonly made use of in this county is turf and peat, of which the bogs furnish an ample supply. In some places English coal is burnt. At Ballinasheen, it sells for a guinea and a half per ton. Wood is remarkably scarce. There are extensive tracts of ground, which might be advantageously covered with plantations, but the advantage is almost utterly neglected. It is only about gentlemen's seats, of which there are extremely few, that this improvement has been carried on with any degree of spirit. It is not improbable that the bogs were formerly forests; but at present one may travel many a mile without seeing a single tree, and Mr Wakefield had heard of bodies being burnt in mats, for want of timber to make coffins. Mr Stewart of the Ards is an extensive planter, but complains of want of encouragement. He plants chiefly the oak, the ash, and the birch. He rejects the Scotch fir, as injurious to the other trees.

Clay is found in immense quantities, and of various kinds and colours. On Murkish mountain there is abundance of siliceous sand, which for some time has been sent to the Belfast glass manufactury; and employed there in place of that which used to be obtained from England. In the bay of Ards, it is supplied for L.2, 3s. 6d. per ton. Within a mile of Letterkenny, and half a mile of Lough Swilly, there is an excellent slate quarry. Lead ore is met with. The mine on the estate of Lord Leitrim is extremely rich. There is also iron stone, coal, anthracite, garnets, marble resembling that which is denominated statuary marble, chalcedony, of which one piece was found weighing 74 lb., and very beautiful granite. Limestone is plenty. There is an extensive tract of it near Ballinasheen.

The rents of this country are, on the whole, exceedingly low. Mr Wakefield makes the average rent to be 7s. per acre; and Mr Hamilton is of opinion, that the rent of land fit for the plough is from 10s. to 20s. per acre. The mountains are of such trifling value as to be let in the lump. In the neighbourhood of Ballinasheen, land lets at from 5 to 8 guineas. From Ballinasheen to Halintree the rent is about L.1, 10s. The town parks of Donegal let at L.5, and land without the town at from 15s. to 30s. The common leases given at present are for 21 years and a life; but the greater part of those which were granted formerly, and are not yet expired, were for 61 years and three lives. Lord Conyngham, and Sir James Stewart, grant their leases for 31 years and three lives. Lord Donegal's leases are for 61 years, and he renews them on a fine. Minor pro-
priests, possessing estates of from L.200 to L.1000 per annum, are much wanted. Wherever such incomes are found, they belong only to leaseholders. Village partnerships, so common in the west of Ireland, are also prevalent in this county. They amounted at one time to not fewer than 500; but they are gradually decreasing. In the Ross estate, Lord Conyngham has 30,000 acres of granite mountain, which bring him not more than L.2200 per annum. Lord Donegal has nearly 100,000 acres in Inishoen. Mr Murray, a gentleman resident in Scotland, has L.10,000 per annum. The Marquis of Abercorn L.9000; Lord Leitrim L.9000; and Lord Erne L.5500.

The condition of the inhabitants in general is mean and uncomfortable. In the mountainous districts it is wretched in the extreme. The people there are dirty, ragged, ill fed, and superstitious. Their habitations are miserable and disgusting, and their habits such as distinguish the lowest stage of civilization. On the coast, Mr Wakefield tells us, that he met with a peasantry who appeared to be native Irish, most of them speaking the original language, and many of them not knowing a word of English, or, as they call it, Scotch. The men wear shoes and stockings, but the women go barefooted. They are different from the people in the inland parts. They have better houses, and are cleaner in their persons.

The principal rivers in this county are the Gubbarra, which has a short south-west course, and terminates on the west coast; the Finn, which rises at no great distance from the Gubbarra, and running almost directly east, passes into the county of Tyrone, where it joins the Foyle at Strabane; the Dale, navigable by small boats for a few miles, from the Foyle to the village of Ballindrait; the Swilly, which loses itself in the lough of the same name; the Erne, which flows from Lough Erne, and falls into the sea at Ballyshannon, where it forms a very rapid though not a high cascade; the Leannan, and several other streams of less magnitude.—There are many loughs or lakes in Donegal. The most remarkable is Lough Derg, situated in the midst of mountains, and in the barony of Tyrugh; and this is remarkable principally for its being the scene of a Catholic station. In the centre of the lake, and about a mile from the shore, is an island containing not more than an Irish acre. There is a cavern there called the Cave of St Patrick, or St Patrick's Purgatory. Thither the Catholics resort during the months of June, July, August, and September, to do penance for their sins, or rather perhaps to express their superstitious veneration for the place; and so popular is the pilgrimage, that at no time in the course of that period, are there ever fewer than a thousand or twelve hundred persons assembled on the island, nor is there almost a single adult individual of the Catholic persuasion in the counties of Donegal, Londonderry, Tyrone, and Monaghan, who has not been there at least once in his life. Those who visit it on this occasion, from whatever distance they come, must travel all the way bareheaded and barefooted. They remain nine days and nine nights. They are allowed eight oat cakes each; they sleep in the open air; and drink nothing but water out of the lake. The last twenty-four hours must be spent in fasting, and in the course of this time they all bathe, and crowd to a wretched foveal adjoining the cave, which has the name of a chapel, there to make their confessions, and perform their devotions. The Catholic Bishop of Clogher nominates a priest and six assistant ministers, to aid the penitents in these sacred exercises. The priest receives one shilling from each person on landing, and the assistants are remunerated by those whom they confess. One is employed the whole day saying mass in the Irish language, and the others in taking confessions. The priest and his condivotors have a laborious but a profitable occupation; and while the poor people are starving on cakes and water, they are feasting on fish, meat, porter, and wine.—This county abounds in excellent harbours. The bay of Strabragy, in the barony of Inishoen; Mulroy bay and Sheephaven, in that of Killmacrenan; the Guidore, and the Gubbarra; Killbegs, and the road at the Rosses,—all afford safe and commodious retreats for vessels. Donegal bay, formed by the high land of Tiellen head in this county, and the Stags of Broadhaven in that of Sligo, is very capacious; but Mr Dalrymple, hydrographer to the Admiralty, has found by accurate survey, that it is not so wide by ten miles as it is laid down in the charts. Lough Swilly is an uncommonly fine harbour, being twenty miles long, from two to four broad, and of sufficient depth for the largest ships of war. The entrance to it is between two high cliffs, and, when viewed at a distance, appears so narrow, as to seem capable of being shut by a pair of floods. It would leave the only bay of Great Britain in perfect security at single anchor.

The lakes and rivers in Donegal contain all the common freshwater fish, as trout, salmon, eels, &c. At Ballyshannon, on the Erne, there is a great salmon fishery. It is one of the largest, indeed, in Ireland. It belonged to Admiral Packenham, and in 1808 was let for L.1200. Salmon are killed here, weighing above forty pounds. The river Lenam also abounds with salmon, which, like those of the Bann and the Bryne, are always in season. At Ballyshannon there is an eel fishery, which, some years ago, let for L.925 per annum. A few years ago, the herring fishery was a great and thriving concern on the Donegal coast. It was carried on under the patronage of the Right Honourable Burton Conyngham, who made an establishment for the purpose in Rutland Island, and by whom a village, and all the buildings necessary for selling and curing the fish, were erected at an expense of L.38,000 from himself, and a parliamentary grant of L.20,000. Every thing was done to promote the undertaking; and so successful was it for some time, that it gave employment to 300 vessels and 1200 boats, and that there were returns in cash of no less a sum than L.135,000. But the herring soon disappeared, and the whole scheme failed. The reason of these fish deserting this part of the coast was thought to be the prevalence of a red animalcule, called the Cancer halecun, with which the whole surface of the water seemed to be covered. About thirty years ago, a whale fishery was attempted with considerable success. The gentleman who engaged in it generally killed two or three, and sometimes four in a season. An unfortunate accident, however, happening to one of the boats, which was dashed to pieces by a whale, and had two of its crew drowned, put an end to this enterprise, and it has never since been revived. At the same time, sun-fish, of a monstrous size, and producing each from a ton to a ton and a half of oil, were caught in great numbers. The average value of a whale was about L.750; that of a sun-fish about L.45. Cod and hake also used to be taken in such quantities, that Mr. Brice, in his Report to the Committee on the Irish Fisheries, makes mention of four men having caught with lines twenty dozen of these fish in two
Donegal.

Manufactures, &c.

hours. But of late years, all the fisheries on the coast of Donegal have, from various causes, very much declined.

The chief manufactures in this county are those of linen, duck, and canvass. The linen, of which a considerable quantity is made, is narrow, not exceeding 32 inches in width. Much of the yarn made use of is spun in the adjoining counties of Londonderry, Antrim, and Tyrone. The amount of yarn sold in the monthly yarn market of Donegal is L.1,500; and in the market of Ardra it is not less than L.2,000. In the years 1807 and 1808, the Linen Board paid the sums of L.165 and L.147, 12s. 3d. as bounty at the rate of 2d. per yard on 19,795 yards, and 17,750 yards of duck and canvass.—On the coast at Ards, there is a sea-weed called slaitk-marrow, which grows to an immense size, and is washed up sometimes in ridges, ten feet high and a mile long. This sea-weed is dried, and burnt for kelp ashes, which sell at from 5s. to 15s. per cwt.

There are no towns in this county of any great consequence. The principal one is Ballyshannon, which stands upon the Erne, and has the advantage of a salmon fishery. Lifford, the county town, is but a small place. Letterkenny, though happily situated at the bottom of Lough Swilly, seems not to have profited by that circumstance. Donegal also, notwithstanding its favourable situation on a fine bay, is of very little note. Killibegs, with similar advantages, is equally insignificant. And Raphoe has no other recommendation, than that of being the see and residence of a bishop.

Weights and measures.

The dry measures and weights are Troy and Avoirdupois; and the liquids are pints, &c. as through the rest of Ireland. From Ballybofes to the sea, potatoes are generally sold by a measure, which is supposed to weigh about 8 stone, 14 lb. to the stone. Oaten and barley meal is sometimes sold by the peck, which contains 28 quarts, and is supposed to weigh 8 stone. Selling oats by measure is abolished.

Donegal is divided into five baronies, viz. Inishoen, Kilmacrenan, Raphoe, Boylagh and Bannogha, and Tyrugh. It contains 42 parishes. Along with the burgus of Ballyshannon, Donegal, Killibegs, Lifford, and St. Johnston, it formerly returned 12 members to Parliament. But since the union, it sends only two, and both of them are for the county. There are 9,000 freeholders. Earl Conyngham and the Marquis of Abercorn have freeholders sufficient, when united, to return the members for this county; but Lord Donegal possesses an estate, which enables him, with good management, to succeed against either of them singly.—There is one regiment of militia.

In this county, which is all in the ecclesiastical province of Armagh, the diocese of Raphoe, according to Dr. Beaufort, has 31 parishes, with 32 churches, comprising an area of 515,250 Irish acres; that of Derry has 11 parishes and 13 churches, with an area of 139,300 Irish acres; and that of Clogher has one parish and one church, with an area of 25,000 Irish acres. The bishop of Raphoe has a revenue of L.800.—in the time of Mr. Young, author of the Tour in Ireland, it was only L.260. The whole of his diocese lies in the county of Donegal. It is 56 English miles long and 40 broad. The chapter is composed of the dean, the archdeacon, and four prebendaries. The see is in the small town of Raphoe, where there is a neat, though not large cathedral, and an old but convenient palace. It is near the one extremity of the diocese, and about 50 English miles from the other. The patronage of six parishes is in the crown; of fifteen in the bishop; of seven in the University of Dublin; and of three in lay lands. Each parish, on an average, contains about 16,179 acres, and 3,950 souls. The greatest proportion by far of Protestants in this county are Presbyterians. The Anti-burgler Seeders have four congregations here, viz., at Taughboney, Cavanoe, Ray, and Rathmelton. The Roman Catholics are numerous, and comprehend the greatest part of the population. The Catholic bishop of Raphoe has about L.1,000 per annum. He is paid by a poundage on the income of his clergy. At Donegal (town) the priests are paid by a bank of yarn; and for confession, they receive a peck of oats, or 2s. 2d. in money, from the head of each family. There are few Catholic chapels; so that the priest and his congregation meet sometimes under the shelter of a rock, or any other that they can conveniently find. The only Catholic of great landed property is Lord Southwell, who has a good estate; and as there is so little property of this kind in the hands of the Catholics, none of them are ever on a grand jury. The militia regiment has not a single Catholic officer. There is a free and friendly intercourse between the Catholic clergy, and the few country gentlemen who reside. Great and disgraceful riots, however, have been from time to time excited by mobs of Orangemen, which have given occasion to trials.

The county of Donegal is about 72 English miles long, and 51 broad; and contains 1704 English square miles, or 1,091,736 acres. According to Dr. Beaufort's estimate, in 1792, there are 23,521 houses, 140,000 inhabitants, 46,556 acres to a house, and about 13.8 souls to a square mile, and nearly six to a house. By the return made to Mr. Bushe, (see Memoirs of the Royal Irish Academy for 1789,) the population of Donegal is stated to be at the rate of 7.35 to a house. The number of houses in 1791, as returned by the inspector-general of hearth-money, was 24,976, of which 15,395 had one hearth, 1,225 had one, 282 had three, 97 had four, 55 had five, 24 had six, 14 had seven, 20 had eight, 5 had nine, 6 had ten, 20 had more than ten and less than forty-four, besides 648 which were exempted as new, and 715 as paupers. The population of Donegal is inferior to that of twenty-nine counties of the thirty-two, which Ireland contains. The proportion of Catholics to Protestants is as six to one; there being 116,667 Catholics, and 23,333 Protestants. See Beaufort's Memoir of a Map of Ireland; Newenham's View of the Natural, Political, and Commercial circumstances of Ireland; M'Parlan's Survey of Donegal; and Wakefield's Statistical and Political Account of Ireland. (+)

DOROENA, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY, p. 136.

DORCHESTER, is in the hundred of Uggescombe, in Dorsetshire, of which it is the county town. Its distance from London is very nearly 120 miles south-west. It sends two members to parliament, a privilege which was conferred on it by 25 Edward I. The right of election is vested in the inhabitants, paying to church and poor, in respect to their personal estates, and also in such as pay to the church and poor, in respect to their real estates within the borough. The number of the voters is about 400. The government of the town is vested in a mayor, 2 bailiffs, 6 burgesses, 6 capital burgesses, a governor, and 24 common council men. The form of the town is an irregular square, though there is reason to believe, that anciently it made a complete one. It consists principally of three spacious streets, which unite nearly about the middle. They are well paved and lighted, and kept remarkably clean; but in this, as
DORCHESTER, Dorset.  

well as most of the other towns in this county, there is a great dulness and want of activity. There are several well constructed and rather elegant buildings of brick and stone; the most remarkable of which are the three churches, St Peter's, Trinity, and All Saints. The town-hall is very spacious and convenient, under which is the market-place; and behind it two rows of butchers' shops. The county hall is remarkable rather for its neatness and commodiousness, than for the taste or elegance of its architecture; and the gaol, which, under the same roof, contains a county gaol, a penitentiary house, and a house of correction. It is built exactly and entirely on the plan so strongly recommended by the late Mr Howard. In its external appearance, as well as in its situation, this building is very striking; and its interior is arranged and fitted up in the manner best suited for its destination. The buildings consist of a lodge, keeper's house, chapel, debtors' day rooms, female fires, and female debtors rooms, visiting rooms for male debtors, felons' infirmaries, &c. Besides the main building, there are four wings, which, though detached, communicate with the centre in each story by means of cast iron bridges. The sleeping cells will accommodate 88 prisoners, and they are distributed in the different buildings. The condemned prisoners are confined in four cells, light and airy; and such as are violent and refractory, are confined to four that are perfectly dark. The male prisoners are completely separated from the female; and the prisoners of each sex are divided into classes, for each of which separate subdivisions are appropriated, by means of distinct stair cases, with courts, work rooms, &c.

Dorchester was formerly famous for its woollen manufacture; but this is now gone to decay. At present it is chiefly celebrated for its ale. The situation, as well as the environs of the town, are very pleasant. It stands on an ascent above the river Frome, (which bounds it on the north side,) about six miles from the English Channel. On the south and west the downs open to the view, rich in pasture, or, where tilled, affording abundant crops of corn. Dry and pleasant walks, planted with rows of lime and sycamore trees, accommodate the inhabitants, and adorn the vicinity of the town on the south and west, and partly also on the north and east. Dorchester was a place of considerable importance in the time of the Romans, as the Via Icniana; on which it stands, and the several vicinal roads which branch from this, as well as the coins, &c. found here, abundantly testify. In 1595, it was visited by a most dreadful plague. In 1613, 300 houses were destroyed by fire, and the loss was estimated at L.200,000. There are three fairs held in it for cattle, sheep and lambs, wool and leather. The market days are Wednesday and Saturday. Its population in 1811 was 2546. (w.s.)

DORDOGNE, the name of one of the departments of France, derives its name from the river Dordogne, which traverses its southern part from east to west. It is bounded on the north by the departments of Upper Vienne and Charente, on the west by those of Lower Charente and Gironde, on the south by that of Lot and Garonne, and on the east by those of Lot and Correze.

The principal rivers of this department are the Dordogne, the Ille, which passes Perigueux, the Hute, the Upper Vezere, &c. Of these, the Dordogne and the Ille only are navigable. The Dordogne is navigable before it reaches Libourne, and the Ille is navigable from Contras to the Dordogne. The country is mountainous and well wooded, and the air is pure, though cold. There are several extensive plains, and very fine valleys, in the department. The soil is generally stony, and more than one-third of it is in cultivation. Corn is raised only on the banks of the Ille and the Dordogne, and, in consequence of the want of meat, chestnuts form the chief article of food for the inhabitants. In some of the cantons there are good meadows, which might be turned to great account in the fattening of cattle. Game, (which is principally red partridges,) fattened poultry, and truffles, which accompany always the turkeys and poultry in Perigueux, if they do not form the riches, are at least the resources of this department. The productions of the soil are corn, maize, wines, of which those of Bergerac and Domme are the most celebrated; truffles, chestnuts, and walnuts. The principal articles of commerce are poultry, pigs, cattle, chestnuts, brandy, timber, iron, knitted hosiery, paper, and earthen ware. The iron mines produce excellent iron, which is used in the common founderies, and supply 63 forges, the most important of which are those of Somerelles, Ans, Eysies, Montenas, and de Lavaur; and there are also several mineral springs in the department.

This department has a superficial extent of 9182 square kilometres, or 480 square leagues. The forests, which are very extensive, though in a state of decay, occupy 60,000 or 70,000 hectares, or about 135,000 or 136,000 acres; of which 64,000 hectares belong to individual proprietors. The average contribution of every individual to the expences of the state is nearly 6s. 6d. sterling; and in the year 1808, the contributions to government amounted to 3,171,612 francs. The following is a list of the principal towns, with their population.

Perigueux is the capital. The total population of the department is 410,350. It is stated at 426,000 in the Almanach du Commerce pour 1811. See Herbin's Statistique de la France; and Chantreaux's Science de L'histoire, &c. (s.)

DORDRECHT, or Dort, Dordrecht, or Dortrecht, is an ancient town of Holland, and is one of the richest and strongest in the kingdom. It is situated at the embouchure of the Meuse, which here takes the name of Merwe. The harbour is commodious, and has from 20 to 24 feet of water at spring tides. Vessels which draw 10 or 12 feet of water can enter it at all times. By means of the river Waal, which passes before the town, great floats of timber are brought to Dordrecht, which can enter the harbour at all tides. These floats are sometimes so enormous, that 500 men are sometimes necessary to conduct them. The timber is cut in the sawing-mills, which are numerous in the vicinity of Dordrecht.

Dordrecht is the magazine for the Rhenish wines, which are brought down the Rhine and the Meuse, for all sorts of iron-work, lime, marble, coal of Liege and Namur, and other articles of merchandise, which are conveyed in boats from Cologne and Gueldres. There are refineries of salt, and bleaching establishments at Dordrecht; and there is a considerable fishery.
particulars of salmon. The position of Dordrecht, according to trigonometrical observations, is in East Long. 4° 59' 42", and North Lat. 51° 48' 54". (j)

DORIA, ANDREW, one of the most celebrated naval commanders in the 16th century, was born at Genoa A.D. 1466. Descended from one of the noblest families in that city, he soon rose to the highest offices in the service of his country; and commanded the Genoese fleet for several years before the republic fell under the power of Francis I. in 1522. From this period he directed the naval operations of the French monarch with great success; and particularly gained a complete victory over the Spanish fleet under Moncada, on the coast of Naples, in the year 1528. In this situation, however, his independent spirit, as the citizen of a republic, and his unceremonious manners as a seaman, gave frequent umbrage to the French courtiers, who employed every artifice to render him obnoxious to their king. When the French began to fortify Savona, with an evident intention to render it the commercial rival of Genoa, the patriotic Doria demonstrated in the highest tone against the measure, and even made an offer of 300,000 crowns, in order to secure the privileges of his native city. His conduct having been represented as unpatriotic in the most aggravated point of view by the French monarch, was treated to such a degree, that he commanded his Admiral Barbiesiaux to sail directly to Genoa, to apprehend Doria, and to take possession of his galleys. Doria, having received timely intelligence of this order, retired with his fleet to a place of safety; and in the height of his indignation, having sent back his commission with the order of St Michael to Francis, he entered the service of the Emperor Charles V. To deliver his country from a foreign yoke was his principal inducement in taking this step, and the object of his highest ambition. Having learned that the French garrison which held the Genoese in subjection, was much reduced by the pestilence, and that his countrymen were ready to second his measures, he landed a small body of men during the night, who surprised one of the principal gates, and gained possession of the city without opposition or bloodshed. Aided by the fame of his exploits, the support of the emperor, and the gratitude of his countrymen, he might, without much difficulty, have rendered himself the sovereign of Genoa; but, sacrificing all views of his own aggrandizement, and claiming no pre-eminence or power above his equals, he remitted the settlement of the state to an assembly of the citizens; and the ancient form of the republic was re-established with universal approbation. In the following year, the Emperor, having landed at Genoa on his way to Italy, honoured him with many marks of distinction, and always had recourse to his abilities in every naval operation of any importance. Having been ordered, about this time, to chastise the insolence of Barbarossa, whose corsairs had committed depredations upon the imperial flag, he attacked a part of the piratical fleet in the port of Sorgee, drove the crews ashore, and brought out nine of their galleys. In 1592, he gained repeated successes over the Turkish fleet, and reduced their principal forts in the Morea. In 1595, he acted as high admiral of the fleet in the famous expedition to Africa, which was conducted by the emperor in person, and which so successfully broke the power of the pirate Barbarossa. In 1541, he again conveyed the emperor to the African coast, after having in vain represented to him the dangers of such a voyage at the season when it was attempted, and having faithfully predicted, as was so fatally verified, the unavoidable destruction of the whole armament. But amidst all his expeditions, he watched incessantly, like a tutelary divinity, over the welfare of Genoa, and even when removed to a distance, was often, by his vigilance and foresight, the means of preserving the liberty which he had established. Beloved and respected by his countrymen, he continued to possess a powerful influence over the councils of the republic; and, while he adhered to his purpose of living as a private citizen, yet from the veneration which he acquired by his virtues, he felt himself in a manner invested with all the authority of a sovereign. While all admired his talents, and respected his disinterested conduct, there were a few who viewed with jealousy his ascendancy in the commonwealth. They had indeed ample security in his age, his moderation, and his love of liberty, that he would never abuse his power, or injure that free constitution, which it had been the chief glory of his life to establish; but they had begun to recognize a formidable enemy to their liberties in his grand-nephew Giancamino, whom he had adopted as the heir of his private fortune, whose gratification and aggrandizement he indulged without bounds, and who gave daily proofs, by his haughty and overbearing manners, that he aimed also at succeeding his uncle in authority and power. Of these apprehensions and murmuring ones, John Lewis Fiesco, Count of Lavagna, took advantage in his ambitious schemes, and formed one of the most daring conspiracies recorded in history against the life of Doria, and the liberty of his country. One of the most illustrious subjects of the republic, and possessed of qualifications to attract the respect and affection of his fellow-citizens, he found means to collect a number of bold adherents, to whom he intrusted his plot, and to secure a multitude of friends, who, though ignorant of his designs, would be ready to support him in power. His object was to assassinate the two Dorias, with the principal persons of their party, and abolish the republican form of government, to proclaim himself Duke of Genoa. By appearing entirely devoted to a life of dissipation, and by paying the most respectful attentions to Doria and his nephew, he completely disguised his design, till they were fully ripe for execution. On the night between the second and third day of January 1547, during the interval between the demission of the doge of the former year and the election of his successor, the conspirators rushed forth to get possession of the gates, to seize the galleys in the harbour, and to attack the palace of Doria. Giancamino, awakened by the noise of the tumults, and imagining it to be occasioned by some mutiny among the sailors, hurried with a few attendants towards the harbour; but, falling in with a party of the insurgents in his way, he was beheaded and murdered on the spot. His uncle, in the mean time, having received intelligence of this event, and of the danger which threatened his own person, instantly mounted on horseback, and saved himself by flight. But Fiesco, in the midst of his success, while passing hastily by means of a plank from the shore to one of the galleys, fell into the sea, and sinking to the bottom by the weight of his armour, perished in the moment of triumph. In his death, the cause of the conspirators received its mortal blow; and the whole body, having lost the spirit by which it was animated, was almost instantaneously dismembered and dispersed. On the following morning the city of Genoa was freed from every vestige of an enemy, and Doria, returning to his residence in the evening, was received by the inhabitants with acclamations of joy. He conducted himself with

the utmost moderation and magnanimity; and the de-

DOR KING, a market town of England, in the coun-

ty of Surrey, and hundred of Dorking, is situated near the river Mole in a sandy vale, sheltered on the north by the ridge of chalky down which runs across the county. The town consists of three streets, the east, the west, and the south, which are tolerably clean, and are well watered with springs. Most of the houses are built on the side of a hill, which consists of a soft sandstone, excavated in many places into cellars. The church, dedicated to St Martin, is 127 feet long, and consists of a nave with north and south aisles, a chancel, and a low embattled tower, containing eight bells with a clock and chimes. The breadth of the nave and aisles is 53 feet, and that of the chancel 191. The body of the church is built of the stone and flints of the county, and the upper part of the tower of squared stone or chalk. The Roman road from Arundel to Dorking, is said to have been often discovered by those who were employed in digging the graves. There is at Dorking a workhouse, and some almshouses, on a pleasant little heath called Colman Dean. The town-hall stands in the middle of the High-street. There are several corn-mills in the neighbourhood of Dorking, and linen is manufactured to a considerable extent. There is a well-supplied weekly market every Thurs-

day, and an annual fair on the eve and day of the Feast of the Ascension. This town has been long celebrated for a kind of fowls with five claws, called Dorking fowls, which are bred and fattened in great quantities, and sent to the London market. One kind is perfectly white, and another of a partridge colour. Numerous mansions and villas are erected in the immediate neighbour-

DORONICUM, a genus of plants of the class Syn-
genia, and order Polygama Superfam. See Botany,
p. 300.

DORSETSHIRE is a maritime county, lying in the south of England, between 50° 30' and 51° 6' north latitude, and 1° 58' and 3° 18' west longitude. Its form is irregular on all sides. On its long northern side, it has a great angular projection in the middle; and its sea coast runs out into points and headlands. If measured across the centre of it from north to south, it stretches about 56 miles; and from east to west it is rather more than 50 miles. Towards the south-west corner, a small portion of it is cut off and surrounded by Devonshire; and, on the other hand, a small part of Somersetshire is inclosed in Dorsetshire. This county is bounded on the north and north-east by Wiltshire; on the south and south-west by Somersetshire, from which, for a little way, it is divided by the river Yeo; on the east by Hampshire; on the west by Devonshire; and on the south by the British Channel. The northern parts, especially on the borders of Wiltshire, are in general level; and on the north-east corner a considerable forest formerly existed, which still retains the name of Cranbow Chase. A ridge of lofty chalk hills runs across the middle, nearly to where the county joins Devonshire. The part bordering on Somersetshire is beautifully varied in surface, and presents many extensive and rich valleys. That part of Dorsetshire which lies next Hampshire, is a dreary barren heath, which likewise stretches along the coast for a considerable way.

In point of size, Dorsetshire, when compared with the other counties of England, may be deemed rather large. It is said from the best authority, to contain of arable land 153,588 acres; pasture land 169,031; mea-
dow 78,628; commons 26,916; downs 31,272; heath land 29,979; woods 12,755; copses 2779; plantations 2020; waste 1586; to which must be added for rivers, water courses, roads, land occupied by towns, farm buildings, &c. 8000 acres: making on the whole 512,154 acres. It is divided into divisions, hundreds, boroughs, liberties, and tithings. There are 9 divisions: Blandford North, or Blandford; Blandford South, or Wareham; Bridport, or Beaminster; Cerne; Dorchester; Shafton East, or Wimborne; Shafton West, or Shaftesbury; Sturminster; and Sherborne. The division of Blandford North comprises three hundreds, one borough, (Blandford Forum,) one liberty, and 82 tithings. The land rate at 4s. in the pound, amounts to L2,138, 6s. 6d. and when a single county rate is raised, the sum paid out of the poor's rate amounts to L32, 17s. 8d. The division of Wareham contains five hundreds, two boroughs, (Corfe Castle, and Wareham,) three liberties, and 65 tithings. The land rate amounts to L3,308, 13s. 7d. and the sum paid out of the poor's rate to L43, 16s. 6d. The division of Bridport contains five hundreds, two boroughs, (Bridport, and Lyme Regis,) four Bridport liberties, and 68 tithings. The land rate amounts to L6,117, 3s. 11d. and the sum paid out of the poor's rate to L59, 16s. 1d. In the division of Cerne, or the subdivision, as it is sometimes called, there are three hundreds, three liberties, and 34 tithings. It contains no borough town. The land rate amounts to L2,562, 1s. 10d. and the sum paid out of the poor's rate to L42, 14s. The division of Dorchester comprises five hun-
dreds, two boroughs (Dorchester, and Weymouth and

DORSETSHIRE.

Melcombe Regia, six liberties, and 81 tithings. The land rate amounts to L. 5980, 8s. 5d. and the sum paid out of the poor's rate to L. 95, 1s. 3d. In the division of East Shaston, there are no liberties and no boroughs; the number of tithings is 62. The land rate amounts to L. 4458, 9s. 4d. and the sum paid out of the poor's rate to L. 66, 13s. 4d. In the division of West Shaston there is not a single hundred, there is only one borough, (Shaftsbury,) and there are only two liberties, and 27 tithings. The land rate amounts to L. 3287, 17s. 4d. and the sum paid out of the poor's rate to L. 31, 3s. 6d. In Sturminster division, there are three hundreds, no borough town, one liberty, and 27 tithings. The land rate amounts to L. 3013, 18s. 10d. and the sum paid out of the poor's rate to L. 44, 2s. 6d. In the division of Sherborne, there are two hundreds, no borough town, two liberties, and 38 tithings. The land rate amounts to L. 1760, 16s. 5d. and the sum paid out of the poor's rate to L. 42, 3s. 6d. From this statistical account, therefore, it appears that Dorsetshire comprises 34 hundreds, 8 borough towns, 22 liberties, and 430 tithings; and that the land rate at 4s. in the pound, amounts to L. 92751, 18s. 6d.; and the sum paid out of the poor's rate, when a single county rate is raised, is L. 500. This county is comprised within the diocese of Bristol. It is divided into five deaneries: Bridport, in which are 48 parishes; Dorchester, in which are 45; Whitechurch, in which are 55; Pimperne, in which are 52; and Shaston, which contains 56; so that in the whole county there are 236 parishes. Dorsetshire lies in the western circuit. The assizes were formerly held at Sherborne, but now they are held at Dorchester.

Climate.

This county is usually represented as the garden of England, though it would be difficult to make good its claim to this character, either in respect to climate or soil. The climate undoubtedly is, on the whole, salubrious, and this it appears to have been accounted in very early times; for it is remarked, that the Romans had more summer stations in this county than in most other parts of England; and the Saxon monarchs built in it a great number of palaces and minsters. But the climate, though undoubtedly salubrious, is not bland and mild as in some other of the western counties; and it has been supposed, that the very circumstance of clearing off the wood, which renders most tracts of land more healthy and warm, in Dorsetshire has rather produced the opposite effect; since as a large portion of the county is exposed, the cutting down the timber would render the air keener and colder, while from the nature of a great part of the soil,(chalk,) there was no occasion for the usual benefit attending this operation, viz., rendering the climate drier. The air on the hills is keen; on the sea coast, more rain falls in winter, and less in summer, than in most other parts of England; and the sea fogs hang on the hills sometimes for a week together. The prevalent winds are the west and southwest, which may be distinctly traced by their effects on the younger trees, which generally bend to the east and north-east. The harvest is not early, seldom commencing, even in the more sheltered spots, and on the richer soils, before the middle of August. The county in respect to soil, is naturally divided into three districts; viz. chalky loam, gravelly sand, and clay of various strength and goodness. The chalk commences as we enter the county from Wiltshire, and runs through the centre of it by Dorchester, nearly to Bridport. In some places, the soil above the chalk is deep and rich, in others thin and poor. The appearance of this district is, in general, smooth and verdant; but there is almost a total want of hedges, timber, and young plantations. The sandy district is the termination of that which extends to Bagshot heath; and though in this county parts of it are by no means unproductive, yet on the whole it is a barren tract. Clays are principally found on the borders of Somersetshire and Devonshire; and in the isle of Purbeck, about Sherborne and Stalbridge, the soil is a rich loam on a chalky rubble. Immediately round Shaftsbury, deep rich sandy loams prevail, of a very light nature, and remarkable for the earliness of their produce. Perhaps the most fertile soils are round Bridport. They consist of a very deep dry loamy sand, admirably calculated for all kind of crops. Some of the valleys in the north-east part of the county are also uncommonly rich, particularly the vale of Blackmoor, (extending from north to south about 19 miles, from east to west about 14, and containing upwards of 150,000 acres,) through which the Frome runs. It consists of a deep rich clay. The soil on the sea coast is either heath, or a thin poor clay, till we reach Abbotsbury, when it improves into a deep loam.

The coast of Devonshire, as it approaches that of Dorsetshire, gradually turns from the south-east towards the south, till it reaches Lyme, when it begins to front the south-west. By this means an immense gulf is formed, which includes the greater part of the south of Devonshire, and north of Dorsetshire; and within this gulf there are several smaller bays principally belonging to this county. These bays are commanded by the isle of Portland, immediately below which the fine bay of Weymouth opens. This is formed on one side by this island, and on the other side by Purbeck, which stretches out to the south-east. When we trace the coast of Dorset beyond Purbeck, the bay of Studland presents itself, fronting the east; and afterwards the great expanse of Poole harbour. In this harbour, a singular appearance is noticed. The singular sea ebbs and flows four times in the 24 hours, twice on the moon is at south-east and north-west, and twice when she is at south by east and north by west. This is supposed to be occasioned by the isle of Brownsea, which lies near the entrance of Poole harbour, obstructing the water. The rivers in this county are neither large nor numerous. The Frome rises in Somersetshire, and flowing south by Weymouth, falls into Poole bay, three miles below the former place. The Stour takes its rise in Wiltshire, and flowing south to Sturminster, afterwards pursues a south-east direction, and meeting with the Avon of Hampshire, it falls into the sea at Christchurch. The other rivers are the Yeo, the Piddle, the Char, and the We.
DORSETSHIRE.

agriculture of Dorsetshire presents few subjects that are very interesting. It is by no means well farmed, except in what respects the management of their sheep, the dairy system, irrigation, and the culture of hemp.

The principal sheep country is round Dorchester, within eight miles of which it is calculated that nearly 200,000 sheep are kept, of which about a fourth part are sold every year principally at Weyhill fair. The whole county supports upwards of 600,000 sheep, of which nearly 200,000 are annually sent out of it. Dorset has long been famous for its breed of sheep. As they lamb in very early season, they are brought up to supply the metropolis with house lamb. They are large sized, with round and bold horns, deep carcase, and short legs. There is no mixture of colour in them if they are pure Dorsets. The Wiltshire sheep resemble them most. They thrive remarkably well on the rich pasture of the downs. Besides this breed, there is a small kind in Portland and Purbeck, the flesh of which is uncommonly sweet. It seldom weighs more than 10 lb. a quarter.

The dairy system of Dorsetshire is peculiar to it, and some other of the south-western counties: the plan is for the farmer to find the dairy-man, as he is called, a certain number of cows, at a fixed sum, which he supports throughout the year. The usual price paid for the use of each cow is from L. 10 to L. 14 annually. Little cheese is made here; but the London market is supplied with large quantities of salted butter, which is reckoned inferior only to the Cambridge butter. The admirable improvement of irrigation is well understood, and very generally practised in this county; indeed it may be said to have been revived by a native of it, Mr Boswell of Fiddletown, whose treatise on the subject is complete and satisfactory in all that relates to it. The watering commences at or before Christmas, and is occasionally repeated, so that in general, by the middle of March, there is sufficient water for cows and lambs; these are grassed till the month of May, when they are taken out, and the meadows again watered; by this plan about the beginning of July nearly two tons of hay per acre are obtained. As soon as the hay crop is off, they are again watered till September, when the dairy cows are put on them till near Christmas. The different cuts for this purpose are made with great judgment; the expense at first is from L. 4 to L. 6 per acre; afterwards there is very little trouble or expense attending them; watermen, as they are called, attending the meadows, to put all the cuts, &c. in order through the winter, for 3 shillings per acre. Hemp and flax are principally cultivated on the deep rich loams near Bridport. From 1782 to 1792, 86,571 stone of the former was grown, the bounty on which amounted to L. 1082. 2. 9. Since the year 1792, the bounty has been discontinued, so that the exact quantity now grown cannot be ascertained; but it is supposed to be very considerably increased. It is calculated that 500 acres are under this plant. Between 1782 and 1792, 301,726 stones of flax were grown; on this the bounty amounted to L. 5028. 15. 4.; at that time 1700 acres were supposed to be under flax; at present it is calculated there are at least four times as many. The only circumstance attending the preparation of flax, either peculiar to this county, or at least not common, is the mode of ripening it. It is not watered in pits or brooks, as in most other parts of England, but exposed for three or four weeks to the action of the dews and rains on the stubble, or meadow-land; hence it is called dem ripened flax. The price of wheat in Dorsetshire, on an average, for a very great number of years, is found to be above the average price of wheat in England and Wales, as inserted in the Gazette, while the price of barley was below the average of the kingdom.

Dorsetshire is rather an uninteresting county to the botanist; on the beach of Weymouth, however, most of the flax that can be found in the south of England are thrown up by the sea: the isle of Portland affords Euphorbia Portlandica in great abundance; and, on the higher parts of the island, Lavatera arborea, tree mallow, is found. Linen is extensive, eschallot, has also been met with here. On the Chesil banks there are several marine plants, particularly Salsola fruticosus, Insula crithmifolia, and Pium maritimum. On the heath between Morden and Wareham, Exacum filifforme (Marsh centaury) grows; this rare little plant, Dr Maton remarks, has never, as far as he knows, been found farther northward; it grows on spots overflowed in the winter. Near the harbour of Poole, Santolina maritima, another rare plant, is met with. On the veins of chert, which form Lulereak cove, Lichen concentricus appears; and on the shore, near the same spot, a singular variety of Fucus nodosus. On the declivity of some chalk hills at Loders, in the vicinity of Bridport, Opurys spiralis (spiral tway-blade) grows in considerable abundance. Dr Pulteney discovered on Hodhill, in Cranborne Chain, Cineraria integrifolia, (mountain flea-wort,) and Dr Maton observed Thesium linophyllum, (bastard toad-flax,) and Ruthia sylvestris, in a wood skirting the declivities of the hill.

Dorsetshire is rather more interesting to the geologist and mineralogist. The western border of the county is nearly the limit of that singular but by no means uncommon phenomenon, which has puzzled all geologists—the occurrence of flints in the chalk. Within four miles of Honiton, in Devonshire, it totally disappears. The extent of this formation, therefore, according to Dr Berger, setting out from London, and going in a direct line from east to west, is about 150 miles; but though this formation still exists far inland, yet it ceases long before in the cliffs which form the sea coast. Flints in the chalk are very conspicuous in the cliffs of the Isle of Wight; but the island of Portland presents a grit, with a calcareous cement; and Lyme Regis a shell limestone. This contains, some very beautiful and large specimens of ammonites, &c. In the Isle of Purbeck, the chalk hills lie in the prolongation of a line westward from the Needles. The hill; on which Corfe Castle stands, consists of what is termed hard chalk. Coarse shelly limestone, which is thought to be very rare in England, is met with in Purbeck and Portland; in some places, it includes patches of a compact limestone, which becomes harder, as it passes gradually into a state of complete flint or chert. In the quarry of Tillywhim, in the isle of Purbeck, the stone is principally composed of shells of oysters that have lost their outside coat. The marine remains, found in the Portland stone, are principally species of Trigonia of Lamarck, a genus of which a living species has been found in the South Sea. The specific gravity of the coarse shelly limestone, Dr Berger found to be, from Swanage quarry, 2.505. Portland north-east quarry, 2.565. Tillywhim quarry, just where it passed into a calcareous sandstone, 2.465. The specific gravity of the composite limestone, from the Tillywhim quarry, was 2.511; and from Portland, 2.511. The specific gravity of chert from Portland was 2.545. Oviform limestone is met with in the quarry of Wardship, in the
The isle of Purbeck has also several valuable stone quarries, the principal of which are in the neighbourhood of Swanage. The stone differs from that of Portland, and is not so valuable or useful. It is principally composed of shells and other marine remains, cemented very closely by calcareous spar. That which is got at Swanage takes a fine polish, and looks like alabaster; formerly a kind of black stone, called Purbeck marble, was obtained. Some fine specimens of it are to be seen in the church at Christ-Church. The pillars of Salisbury cathedral are also made of one species of Purbeck marble. The hills, out of which the stones are dug, run nearly east and west. Near the shore, they are 400 or 500 feet high, and higher inland. The dip is very considerable to the north, the uppermost bed of stone lying near the surface, while, in about 300 yards, it sinks below the sea. The average export of this stone is about 40,000 tons. It is mostly used for flag-stones for paving; and the greatest part is shipped from Swanage for London. The price is about 40s. per hundred feet superficial. The thickness is generally from 2½ to 3 inches; and reckoning that 14 cubic feet are a ton weight, a hundred superficial feet will weigh about 1½ tons. The men employed in digging the stones are about 300. The ground rent paid to the owners of the land is about 6d. per ton for all kind of stones raised here.

Potters' clay is found in great abundance, and of excellent quality, in the northern division of the isle of Purbeck; and it probably forms the substratum of the whole tract, which may be called the Trough of Poole. The existence of alumine, lime, magnesia, oxide of iron, and silica, has been detected in some specimens of it; but, in general, it is very free from these substances. It feels greasy and smooth, and varies in colour from ash grey to blue. It contains sometimes cylindrical blue nodules, (to which the workmen give the appellation of pins,) the texture of which is close, and the composition probably more ferruginous. The specific gravity of the purest specimens is about 1.723. The principal pits are to the west of the road between Wareham and Corfe Castle, where the stratum extends about three miles in length, and one in breadth: the depth, as well as the quality, varies very much. Farther to the east is a kind of clay of a brown colour, which shrinks very much in the fire. It is reckoned that about 20,000 tons are annually exported, principally for the use of the potteries in Staffordshire. The inferior kinds are sent to London and Bristol, to make brown stoneware. The goodness of the quality depends chiefly on the small proportion of iron which it contains; where there is much of it, the clay will not burn white, and the particles of iron cause it to blister. Upwards of 100 men are employed in the clay pits; many more were employed before an iron rail-way was constructed, from near Corfe Castle to a small harbour opposite Poole; to which it is carried in boats, and shipped thence for Liverpool, London, &c. As the digging of the clay requires great care and attention, it is seldom done by piece-work, but commonly by the day. Three shillings and sixpence is the usual wages. It is delivered in Poole harbour at 20s. a ton, and 2½ cwt. extra is allowed, on account of the loss of weight which it experiences. A species of chalk, found near Rampisham, deserves notice: it seems a kind of Tarras, as it has the quality of growing (as it is termed) under water, i.e. it swells, and at the same time becomes harder.

Dorsetshire is not a manufacturing county. In the
DORSETSHIRE.

Manufactures.

neighbourhood of Bridport and Beaminster, the hemp which is grown there is made into twine, netting, ropes, cordage, sail-cloth, sacking, &c. About 9000 people are said to be employed in these manufactures. At Sturminister Newton, 700 or 800 people are engaged in the manufacturing of swansdown; and at Sherborne, Stallbridge, and Cerne Abbas, there are several silk mills. But the manufacture (if so it can be called) most frequently met with in Dorsetshire, is that of shirt buttons. Shaftsbury and Blandford may perhaps be considered as the centre of this business, though it spreads nearly over the whole county, and is the principal employment of the women and children. The casting, or covering the wire, is done by children, six or eight years old; they are afterwards filled, as it is termed, by more expert hands. It sometimes happens that an active and experienced woman will make twelve dozen of these buttons in a day; the price is about 3s.; but the common quantity made in a day is six or seven dozen.

The principal foreign trade of this county is carried on from Poole, where nearly 200 sail are employed in the Newfoundland fishery. The foreign trade, however, was much more extensive and valuable before the American war. From this port are exported to Newfoundland, provisions, nets, cordage, oil-cloth, and wearing apparel. The imports are principally cod and salmon, dried and salted, which are afterwards shipped to foreign markets; oil, seal-skins, fir, and cranberries. The exports of Portland and Purbeck have been already noticed. From Bridport there is a trifling export trade to Newfoundland, and other parts of America and the West Indies, of cordage, twines, &c. Coal and culm, for burning limestone, are imported into the county to a considerable extent. There is but one iron rail-way, which has been already noticed, for carrying the clay from Purbeck. The declivity of the road is in some places four inches, and in others five, for every twenty yards. The expense of making it was about £2000 a mile. The whole length is 33 miles. Three horses draw 10 tons to the sea side, three times a day, at the expense of about 6d. a ton. There is also only one canal, the Dorset and Somerset, which commences at Gains Cross, in the parish of Shillingstone Okeford, in the former county; and after passing through part of Somersetshire and Wiltshire, communicates with the Kennet and Avon Canal, near Wiltsbrooke, in the latter county.

Dorsetshire is distinguished for its sea prospects; many of which are uncommonly extensive, and partake of all that magnificence with which the sight of the ocean impresses every beholder. Its land prospects, except in the north, and north western parts of the county, are rather bare and unvaried; but where the rich valleys can be taken in, along with the chalky hills and downs, they are very beautiful and impressive. One of the finest inland prospects is seen from the hill on which Shaftsbury stands: "in front, an eminence, called Pendle Hill, rises with a beautiful wooded summit, bounding the fertile vale of Blackmoor, through which a white road, sometimes losing itself among woodlands, and sometimes traversing verdant pastures, winds westward into the distance. On the left, a fine undulating ridge shelters the vale; while the hills of Mere, in Wiltshire, with Alfred's Tower at the extremity; the Tor of Glastonbury, and the lofty heights of Quantick, in Somersetshire, range themselves in the remaining part of the horizon."

The most interesting natural curiosities in this county are the Chesil Bank; the Agglestone; and the Lynches, or Lynchetts. The Chesil Bank unites Port-

land to the Main; it is nearly 17 miles in length; and in some places nearly a quarter of a mile broad, so that it is perhaps the longest ridge of pebbles in Europe, except that of Memel. The pebbles are extremely loose; they consist, in general, of what are called Portland pebbles, of a calcareous nature; but there are many of jasper, chert, quartz, &c. They diminish gradually in size as they approach the main land, being not larger than horse beans near Abbotsbury, while, near Portland, they are from one inch to three inches in diameter. About five or six feet beneath the surface of the pebbles, there is everywhere strong clay, exactly similar to what is found on the beach. Beneath this bank, and the Weymouth side, a narrow arm of the sea runs, called the Fleet. Although the force of the sea frequently washes these pebbles over into the Fleet, yet the depth or breadth of this does not appear to be diminished; indeed the origin and present appearance of this bank is extremely difficult to be accounted for. The Agglestone is an extraordinary insolated rock, situated on the heath, near Studland, in Purbeck; its height is about 20 feet, and its circumference about 80; the shape nearly that of an inverted cone. From the circumstance of the spot where it stands being raised like a barrow, it has been supposed to be a British monument; but Dr Maton, with more probability, conceives it to be a natural rock, composed of ferruginous sandstone. The Lynches, or Lynchetts, are met with in many places, on the downs, both of this county and Wiltshire; they are singular natural terraces, never occurring except on chalk hills, and on some limestone soils, where, however, their appearance is very faint. Between Shaftsbury and Blandford, they are very conspicuous. They are always narrower in proportion to the steepness of the ascent; where the declivity is trifling, the areas are very broad, and the ridges diminish in sharpness; they generally run parallel to the course of the valley below; and where the valley presents great inequalities, or the hill on which they are irregular, they cross one another, and run in all directions. Dr Maton supposes that they owe their origin to subsidences of the ground in a state of solution.

Of the Antiquities of Dorsetshire, the Fia Iceniana: Antiquities. Maiden Castle, near Dorchester, one of the finest Roman encampments in the west of England, for size and strength; a Roman amphitheatre, near the same tower, which it is computed could have contained upwards of 12,000 people; and Corfe Castle, and Wimborne Minster, in which the transition of the Saxon into the Gothic arches may be distinctly traced, are the most curious and interesting.

At the time of the invasion of Britain by the Romans, History. Dorsetshire was inhabited by the Deceangli, a name supposed to be derived from two British words, dweyr, water, and irig, an inhabitant; it formed part of the Roman division of Britannia Prima. The Saxons changed its name to Dorseta, retaining the British word dweyr, and adding the Saxan term setta, a dweller. It constituted part of the West Saxon kingdom; and after the dissolution of the Heptarchy, became the favourite residence of Egbert and his successors. The Danes invaded it early in the reign of this monarch, and an obstinate battle was fought on the banks of the Char, near Lyme. From the period of the conquest, till the civil wars between Charles and his Parliament, the history of this county presents nothing interesting. During these wars, it adhered zealously and firmly to the side of the king; and the clubmen of Dorsetshire,
as they were called, harassed the forces of the Parliament, long after the rest of the kingdom had submitted to their power. In 1685, the unfortunate Duke of Monmouth landed at Lyme.

The following returns respecting this county were made to parliament in compliance with the Population Act in 1811.

| Houses inhabited | 28,210 |
| Families occupying them | 26,821 |
| Houses building | 171 |
| Families employed in agriculture | 12,890 |
| not comprised in these classes | 4,232 |
| Males | 57,717 |
| Females | 60,976 |
| Total population in 1811 | 124,693 |
| Population in 1801 | 119,100 |
| Increase | 5,593 |

DOUAY, Douai, or Duacum, is a town in the Netherlands, advantageously situated on the navigable river Scarpe, which communicates by canals with Lille, St Omer, Dunkirk, and the Northern Sea, and by means of the Scheldt with Valenciennes, Cambrai, and Tournay.

The principal buildings are a very handsome square, a fine arsenal, a school of artillery, a lyceum, a society of agriculture, the church and town-house, a public library, a theatre, and a cabinet of natural history. In the church of the village of Loin, which is close to the town, there are many tombs of the middle ages, remarkable for their sculpture. Douay has long been celebrated for its English colleges, to which the Roman Catholics of England were generally sent to be educated.

The principal manufactures carried on at Douay are those of cambric, camlet, woollen and cotton coverlets, flannels, hats, starch, tobacco, oil, soap, earthen-ware, glass bottles, thread, thread lace, and gauze. Two thousand two hundred and four pieces of cambric were annually manufactured here before the revolution, each about two-thirds of an ell wide, and twelve ells and a half long. The annual amount of its linen manufacture was 271,140 francs. There are also at Douay several salt works and houses for refining sugar, a foundry for cannon, and a manufactory for white-iron goods, which are in great repute. Douay is the entrepot for the flax trade, with all the departments of the empire. The canal from Douay to Lille was completed in 1686, by Louis XIV. There are two annual fairs here, the first of which is held on the 1st of August, and lasts only a day; while the second, which is held on the 1st of September, lasts nine days. Population, 18,500. (m) DOUBLE STAR. See Astronomy, p. 680. and 819.

DOUBU. See Electricity.

DOUBUS, the name of one of the departments of France, which derives its name from that of the principal river, which washes it in the direction from south to south-west. It is bounded on the north by the department of the Upper Saone; on the west by those of Upper Saone and Jura; on the south by the department of Jura and by Switzerland; and on the east by Switzerland and the department of the Upper Rhine.

The principal rivers are the Doubs, the Dessobour, the Loue, and the Ognon, none of which are navigable. The two first are scarcely floatable. The Doubs rises in Mount Jura, near Morteau, below Pontarlier, and passes by St Hippolyte, Montbeliars, Beaumes-les-dames, Besançon, and Dole, and falls into the Saone, near Verdun, after a course of about 180 English miles.

The department is diversified by hills and plains. It is almost arid towards Switzerland; but is extremely rich in the canton above the river Doubs, and near its confines with the department of the Upper Saone. It produces wheat, oats, vines and cheese, and affords pasture for cattle. It contains mines of coal and iron, and quarries of marble and slates. The principal iron mines are those situated in the communes Oye, Palaiz, La Cluse, Mijoux, Monperreux, Metabief, Longeville, Noirefontaine, Pont-de-Roide, Cuize, Cutriel, Ornans, Rougemont, La Brethiere, &c. They supply 6 furnaces, 29 small forges, 31 martins, 3 manufactories for iron wire, and 2 foundries. There is also freestone and abundance of turf in the department. The marshes near Besançon, Ruffy, Morteau, Pontarlier, &c. are extensive.

This department has a superficial extent of 5340 square kilometres, and 270 square leagues. The forests occupy 124 or 125 hectares, or 244 or 245 arpents, and belong almost wholly to individual proprietors. The average contribution of each individual to the expense of the state, is about seven shillings sterling. The contributions in the year 1809 amounted to 1,886,853 francs.

The following is a list of the principal towns, with their population:

- Besançon: 30,000
- St Hippolyte: 5,050
- Pontarlier: 3,880
- Beaumes-les-dames: 2,300

Besançon is the capital. The total population of the department is 227,075. See Herbin's Statistique de la France, and Chantreux's Science de l'Histoire, &c. (x)

DOVER, a seaport town of England, in the county of Kent, and one of the Cinque Ports, is situated upon the English Channel, in a valley almost encircled with lofty chalk hills. The form of the town is remarkable, and has a very romantic appearance when seen from the surrounding heights. It consists of three long streets, stretching in the directions, east, south-west, and north, and converging to one point. The town is divided into the two parishes of St Mary and St James, which have churches of the same name.

The church of St Mary's, which is supposed to have been built in 1216, is a spacious edifice. It consists of a nave and aisles, with a tower at the west end, and is about 120 feet long, and 55 broad. The architecture of
the west front is Norman, and likewise the first three arches, and the columns which sustain them on each side of the nave: the two next arches on each side are elliptical, the most eastern one having a very large span. Beyond these, on each side, are two pointed arches of unequal size. The Norman columns have fluted capitals, and most of the columns are large and massive. A very fine organ was erected in 1742. The galleries are large, and the church is well paved.

St James's church, which is of Norman origin, is an irregular building, with a square tower at the west end. It formerly belonged to Dover castle, and the courts of chancery and admiralty for the Cinque Ports are still held in it.

Besides these two places of worship, there are meeting houses for Baptists, Methodists, Quakers, &c.

A new and handsome custom-house has recently been built, and an elegant hospital has been newly erected, near Archcliff Fort, for the soldiery. The town-hall, which stands in the market-place, is adorned with several good portraits, and a curious print of the embarkation of Henry VIII. for France. There are likewise in Dover, a neat assembly-room, a theatre, and two circulating libraries. In the Apollo library, there is a handsome public reading room, furnished with the London papers, with music and musical instruments. A good free school was established here in 1771, and a charity school in 1789.

Dover castle occupies nearly the whole summit of the high eminence which bounds the south-east side of the deep valley in which the town is built. This eminence is steep and rugged towards the town and harbour, but towards the sea it is a precipice 320 feet in height. The castle consists of a lower and an upper court, defended by ditches communicating with the inner towers. The lower court, excepting on the side next the sea, is encircled with an irregular wall, called the curtain, which is flanked at unequal intervals with a number of towers, the workmanship of different ages. None of these towers are supposed to have been built by the Normans. The 1st tower, commencing from the cliff on the western side, is called the Old Tower, and had formerly a gate and drawbridge. 2. Albrancis, or Rokesley tower, is of a pentagonal form. 3. Chilham, or Calderscot tower, is of a square form, and was built by Fulbert de Lucy. 4. Hurst tower, is named after a dependent manor in Chilham parish. 5. Arsic, or Sayes tower. 6. Gatton tower. 7. Peveril, Beauchamp, or Marshall's tower, built over a Saxon gate-way, is connected with a drawbridge, the abutments of which were discovered about 20 years ago. 8. Porth's, Gasting's, and Queen Mary's tower. 9. Fiennes tower, through which is the principal entrance into the lower court; it is generally called New Gate, to distinguish it from the ancient entrance. On the right of this tower are the apartments of the governor and lieutenant-governors, together with an armory of small arms. There are also modern barracks for the soldiery about this entrance. 10. Clopton's tower. 11. Godshoe tower. 12. Crewequer's, or Craville's tower, is remarkably magnificent. There is a subterraneous passage by this tower, leading to a very large vault, which is defended by a moat of prodigious depth, and a drawbridge, and also by a kind of round tower. In an angle opposite to this tower, is an advanced work called the Barbiian. 13. Fitzwilliam's or St John's tower. A spacious sally-port was formerly connected with this tower, and in the underground passage were a gate and portcullis, the stone grooves of the latter being still visible. 14. A common watch tower. 15. A common watch tower. 16. Averancher's, or Mauzel's tower, stands in an angle formed by the curtain wall, and is a fine specimen of Norman architecture. 17. Veerville, or Finsister tower. 18. Goodwin's tower. 19. Ashfordian tower. Beyond this are three other towers, or rather platforms, that have no particular name.

In ascending from the lower to the upper court, the road is steep, and leads to King's Gate and Bridge, forming the entrance to the upper court, which is encircled with a strong wall and numerous towers. On the eastern side are three towers which command the whole vallum and ascent to the principal entrance of this court. The other principal towers, are Suffolk tower, which is a stately fabric and old arsenal tower, and a variety of others which we cannot find room to notice. The keep, or palace tower, which stands in the centre of the upper court, is in very good preservation, and is used as a magazine. The walls are from 18 to 20 feet thick, and contain the galleries. The summit is embattled, and has a turret at each angle. It is nearly 92 feet high, and about 466 feet above low water mark.

When the public were alarmed with the threats of invasion by the French, government erected many batteries for the defence of Dover castle, and furnished them with a formidable train of artillery. They consist of casemates excavated from the solid chalk rock, covered ways, and subterraneous apartments, capable of accommodating 2000 men. A new road has also been made from the town to the top of the hill. Since the renewal of hostilities in 1803, the heights on the western side of Dover have been defended by strong fortifications, connected by the town by a military road. The other fortifications are Amherst battery at the north pier head, and Archcliff fort at the end of the pier.

The harbour of Dover has at different periods received very great improvements, and is now in a very respectable condition. The encroachments of the sea are prevented by several jetties erected towards the cast, and though large quantities of sand are thrown up at its mouth by the south-west winds, yet with the aid of the backwater, the sluices have been able to clear it in one tide. Vessels of 400 or 500 tons may now enter the harbour in safety; there being a depth of 18 or 20 feet of water at spring tides, and of about 14 at neap tides. The piers which form the harbour are very long and substantial, and are defended by strong batteries continued in a chain along the coast, with numerous martello towers.

As Dover is the principal place of embarkation for the continent in time of peace, its trade is very extensive. Before the commencement of the last war, 30 vessels, of 60 or 70 tons each, besides packets, were employed on the passage to the French coast. They were reckoned the handsomest and most commodious vessels in the kingdom. With a favourable wind the passage has often been made in three hours, and sometimes in two hours and 40 minutes. The breadth of the Channel is 74 leagues.

The principal antiquities in Dover, are the Roman pharos and the ancient church which stands on the upper part of the castle hill. The pharos has externally the form of an octagon, and is a square within. Each side of the octagon and of the square is about 14 feet, and the thickness of the wall below is nearly 10 feet. On the east side is an arched doorway about six feet wide, and on the other three sides of the inner square are narrow spaces for windows, about 13 feet in height. This ruin is now in a state of great decay. The roof is
Dover.

Soil. — The soil is chiefly loam, mixed sometimes with clay and sometimes with gravel, having always a considerable quantity of stones in it. The mountainous region of Mourne and Sliebb-Croob is rude and unkindly, scarcely capable of cultivation, though yielding a good deal of rough pasture. Of course there are some parts of it absolutely barren. Near the banks of rivers, the land is principally in the state of meadows, occasionally overflowed, and thus kept in good condition. In the valleys formed by the mountains, there are turf bogs, which, as storehouses of fuel, are valuable to the proprietors. Some of these bogs have, by means of irrigation, been converted into excellent meadow. The climate is sufficiently favourable to vegetation of every kind.

It is impossible that agriculture can be in a very flourishing condition, where land is so minutely divided as it is in this county. Such a minute division, owing partly to the practice of tenants portioning each child with a share of their farm, and partly to the desire of the landlords to increase their political interest, by multiplying the number of freeholders, narrows the field of enterprise and industry. The absence of the most powerful stimulus to skilful exertion, lowers the respectability of the farmer, and prevents the adoption of any liberal and improved system of husbandry. Accordingly, though in particular spots the ground is well and successully cultivated, we in vain look for those results in respect both to quality and quantity of produce, which a knowledge of the natural advantages of the county, combined with a judicious mode of management, would warrant us to expect.

Wheat has been little cultivated in the province of Co. Down, and it is more frequently found on the sea coast than in any other place. Spring wheat has been sown with advantage. A great deal of barley and some turnips are raised. Oats abound everywhere.
Potatoes, of which there are here from twenty to thirty different kinds, are in Down, as in other parts of Ireland, in great request. They are frequently planted in turf bogs and moory grounds, which are thought to preserve them from degenerating; and accordingly, as the curr is in these cases little known, they are sought for seed by those who have not the same advantage. Flax is sown to a considerable extent. In 1800, there were sown with flax 2700 acres, which were supposed to produce 3200 bushels of flax-seed, and of these, bounties were likely to be claimed for 3000 bushels, to the amount of L.750, being at the rate of 5s. per bushel. Of hemp, there are but a few acres in the whole county. Grasses are grown in great variety and plenty. The following Table gives a view of the average quantity of seed and produce of various sorts of grain, taken from different estates and different years.

Dung and straw manure is universally employed. Marl has been applied with great success. All along the coast, wreck or sea-weed is used for potatoes, and also in some cases for grain. That species of bog which is unfit for fuel, by wanting the necessary adhesion, is applied to sharp as if clayey soils, both by itself, and after being mixed with lime and dung. Lime, limestone, gravel, and shell sand, also, are made use of in manuring the ground.

Down cannot be considered as a grazing district. Yet many cattle are annually fattened in it; and some of these are of a large size, especially on the western side, where the soil is of a deep loam or clay. In general, bullocks are thought too heavy for the soil, and therefore the grazing stock, for the most part, consists of such calves and heifers as are deemed best for fattening and milking. The farms are so limited, that no extensive dairy is kept, but there is a great number of cows; each occupier keeps at least one, and, as he consumes only the skimmed milk in his family, a large quantity of butter is made, which is partly consumed in the county, and partly exported from Newry and other places. The usual quantity of milk obtained from a cow for two months after calving, is from twelve to twenty quarts. To produce twenty, it requires the animal to be a good one, and to have the best pasture. The breed of cattle in this county is indifferent. Little or no attention is paid to it. The prevalent breed is the long-horned, with their horns growing upwards and thick, having large bellies and thin hips, and weighing between three and four hundred weight. They are good milkers, which is here the great object. Some cattle of a superior kind are to be found in the hands of private gentlemen.—There are no flocks of sheep, except among a very few gentlemen. The little farmers purchase them singly or in pairs at the summer fairs, and keep them one or two years, as they find it convenient, fattening them in the house on boiled potatoes, oats, and hay, and then selling them to the butcher, one or two at a time, as they themselves had bought them. The mutton is said to be remarkably sweet. In the mountains there is a native breed of sheep, small and hardy, most of them horned, who are esteemed for the fineness of their wool, and the delicacy of their flesh.—In the mountainous barony of Mourne, great numbers of horses are bred.—Goats are to be seen around the greater part of the cabins. They furnish the poor people with a considerable quantity of good rich milk.

—Habbits, considered as stock, are chiefly to be met with in the neighbourhood of Dundrum, the sandy soil of which is peculiarly suited to them. They are also to be found in various other places in smaller numbers.

—Bees thrive uncommonly well in this county. The dry hills covered with heath and odoriferous herbs, afford them a rich supply of food, and their honey is here highly esteemed for its flavour.—Pheasants, so scarce in all other parts of the kingdom, abound at Tullamore Park, the property of Lord Roden.

Labour in this county is usually paid in money. The general wages of a man are from 1s. 1d. to 1s. 4d. per day. Few women are employed, except in harvest, when they receive 2s. 2d. per day. A man the year round receives about L.18, and a woman L.9; children per day, 6d. A carpenter per day, 3s. 3d.; mason do. 3s.; plasterer do. 3s.; plumber do. 3s.; tailor do. 3s.; shoemaker do. 2s. 6d.; fiddler do. 1s. 4d.; joiner do. 1s. 4d.; mason per perch 2s. 1d.; slater per square 2s. 6d.; blacksmith per lb. 6d. The prices of articles are as follows:

- Car and horse per day 3s. 3d.
- Saddle horse per day 4s. 10d.
- Plough do. horses and man fed, 5s. 8d.
- Mowing grass per acre 7s. 0d.
- Cow's grass per week, 3s. 1d.
- Horse's do. 5s. 2d.
- Iron per stone 2s. 6d.
- Fencing per perch 2s. 3d.
- Turf per piece 2s. 6d.
- Coal, best Wigan, per barrel 5s. 6d.
- Oak per foot 8s. 11d.; ash do. 5s. 6d.; hickory per thousand L.1, 13s.; lime per barrel 1s. 8d.; car m. L.6, 18s. 3d.; potatoes per stone 2s. 3d.; salt butter per cwt. L.6, 5s.; fresh do. per lb. 1s. 1d.; hay per ton L.4, 5s.; whisky per gallon 9s. 4d.; porter do. 1s. 6d.; ale per quart 4d.; beef per lb. 5s.; mutton do. 7s.; veal do. 8d.; pork do. 4d.; eggs per score 7d.; cheese per lb. 8d.; shoewing a horse 3s.; brogues per pair 6s. 8d.; shoes do. 9s. 9d.; leather per lb. 2s.; salt per stone 1s. 2d.; a spade 4s. 3d.; Swedish iron per cwt. L.1, 8s.; undress flax per cwt. L.4; wool per stone 19s. 6d.; land carriage to Dublin per cwt. 4s. 2d.; fowls per pair 1s. 1d.; a turkey 2s. 10d.; a goose 2s.; wheat per barrel L.2; barley per do. L.1, 2s. 9d.; oats per do. 1s. 6d.; flour, firsts, per cwt. L.1, 12s.; do. 2ds. do. L.1, 10s.; do. 3ds. do. L.1, 8s.; oatmeal per do. 1s. 7d.; rabbits per pair 1s. 1d.; milk per quart 2d.; corn acres of oats per acre L.7, 15s.; of meadow per do. L.5, 13s. 9d.; potato land per do. L.4, 11s.; salt per bushel L.5.

In 1802, Mr. Dubourdieu estimated the average rent of the cultivable land at L.1 per Irish acre; so that, calculating the cultivable land to be 300,000 acres, he made the whole rental of the county to be L.300,000. Since the period at which this estimate was taken, the value of land has been greatly increased; and Mr. Wakefield is of opinion, that taking all things into account, the whole rental may now be set down at double of what Mr. Dubourdieu thought it. Several intelligent gentlemen say, that the average rental of the county may be fairly computed at L.2, 2s. per acre. In 1793, land was let for thirty-one years, or two lives, at 1s. 3d. per Irish acre. Now, it lets at two guineas per acre for twenty-one years. Lord Dufferin lets land during three years for one half the produce. It is thought that Lord Moi-
The principal rivers in this county are the South Bann and the Lagan. The Bann issues from the Mourne Mountains, and, taking a north-west direction, enters the county of Armagh, a little beyond Guildford. Its water is remarkably pure, and esteemed superior to any other for the purpose of bleaching. The Lagan rises in the Slieve-Ricism Mountains, flows in a north-east direction between the counties of Down and Antrim, and loses itself in Carrickfergus Bay, not far from Belfast, from which it is navigable a considerable way up. There are several other smaller streams, which contribute both to the beauty and prosperity of the country. Of these, the most important is the Newry, which rises in the Mourne Mountains, and, after a short course, falls into Carlingford Bay. It is united to the Bann by means of the Newry Canal. Small lakes are scattered up and down. Strangford Lough is a salt water lake, occupying upwards of 25,000 acres, and connected with the Irish Sea by a narrow strait, through which the tide rushes with great rapidity and force. There is no very large harbour. Newry affords accommodation to a good number of ships, and by means of the canal, carries on a great deal of trade. Bangor and Donaghadee are artificial harbours. The ports of Strangford and Killyleagh on the Strangford Lough, and the bays of Killogli and Dundrum, admit vessels of a small size.

Coal, both English and Scotch, is imported for fuel. The latter is made use of for melting. The people prefer turf, on account of its greater cleanliness, even when the coal can be obtained at a moderate price. The demand for it, therefore, is so great, that the bogs, of which there is not a great number, are insufficient to answer it, and it brings a price nearly double of what can be got for it in some other counties. No wood can be afforded for burning. Plantations are scarce, and used as embellishments around family mansions. Here, as in many other parts of the kingdom, there are evidences of wood having abounded in former times. A great many fossil trees have been dug up from the bogs. Of these there are two species, viz. the fir and the yew, which are now seldom or never found growing naturally. The natural wood of the county consists of oak, ash, alder, hazel, mountain ash, birch, holly, white thorn, and the grey willow. The fir, the oak, and the yew, are the only trees which are found in the fossil state, fit for use. There are some oaks in this county which never bear acorns. At Moyallan, oak sells at 6s. per square foot, and ash at 4s. Near Tandragee, an acre of eighty years old timber sold for as much as twenty-five adjoining acres of land. The larch is found to grow well in spots, which for any other purpose are comparatively useless. Evergreens thrive remarkably well, particularly on the coast. Myrtles there grow to a considerable size, though quite exposed even during the winter. Orchards are rather on the decline. In the bleaching districts, a small one is attached to almost every cottage.

Manufacturing is carried on in this county to a great extent. Of the quantity of linen produced, and of its value when fit for market, we have no sufficient data for making an accurate calculation. But some idea may be formed, by attending to the quantity bleached on the Bann in 1808. On an average, the twenty greens bleached 8000 pieces wide each, which makes the whole to have been 160,000. The "ground cost" was £2, 10s. The bleaching cost 8s.; the profit was 8s. per cent. At £2, 18s. the 160,000 pieces would amount to £1,650,000; and if to this be added the 8s. per cent. of profit, the total value of the linens annually finished on the Bann will be £2,060,650. The next manufacture in importance to linen is that of muslin. It was scarcely known about thirty years ago; but it has since that time made a very rapid progress, and arrived at a very flourishing state, though occasionally it has suffered depression. It took away many weavers from the linen business. Besides muslins, of every degree of fineness, and of every requisite breadth, various other stuffs are manufactured from cotton, such as callicoes and wrappings, thicksets, corduroys, and velveteens.

In 1805, the Linen Board paid to Francis Cruikshank a bounty on 16,899 yards of duck and canvass, which at 3d. per yard, amounted to £2.11. 2s. 1d. A weaver of fine linen (in 1802) would make, if he was a good workman, from 1s. 4d. to 1s. 6d. per day; and of coarse, from 1s. to 1s. 5d. The earnings of a muslin weaver, when he had constant employment, was from 1s. to a guinea per week. Machinery for spinning linen yarn was introduced into this country by Mr Cruikshank; and it now supplies the greatest proportion of that article which is used in the manufacture. A very considerable quantity, however, is still spun by the hand, of various degrees of fineness, and of excellent quality. In the Belfast Magazine for 1800, there is an account of the exploits of a woman in Downshire, in this department of industry, which are truly wonderful, and deserve to be recorded. Her name is Anne M'Quillin; she resided at Comber, in the barony of Castle-Reagh. In the time of frost, high winds, and excessive drought, she spins what she calls coarse yarn, that is, from 24 to 36 hanks in the pound. But during mild weather, she can spin to the extent of 100 or 105 hanks, which is equal in length to about 214 English miles out of the pound of flax. Of this latter, she produces a hank in nearly two weeks. A considerable part of the linen yarn manufactured in Down is spun in Tyrone and Derry.

Herrings have been frequently caught in great numbers in Strangford Lough; but they were not so good either in point of fitness or flavour as those taken in the main sea. They sometimes come close to the shore, but generally they are found towards the Isle of Man, where the boats from Newcastle pursue them. These are excellent in quality. Many of them are brought to Down, and sold through the country by the fish carriers. The coast of this county abounds with whiting, gurnard, sea-trout, mackerel, and haddock. About the Copeland Islands, which lie off Donaghadee, there is found a small red codling, which is better tasted than the common cod, but does not answer so well for salting. At Bangor, there is a fishery of sole, plaice, and turbot; and, in winter, of cod and oysters. From various quarters, boats come and trawl in Dundrum Bay for turbot, sole, plaice, cod, and haddock, of which they carry off large quantities. In all this fishing, the inhabitants of the coast of Down have very little share. They neither have sufficient enterprise nor proper apparatus, otherwise it might be a valuable source of subsistence and wealth to them.
got in the barony of Mourne, the lordship of Newry, and in part of Upper Ivecagh. Along the face of the mountains there are several quarries of it, and, from the little river Annapolis, it is exported to other places on the coast. There is also excellent freestone, the chief quarries of which are those of Scraba, near Newtown, and those of Kilvarin on the road from Hillsborough to Moira. This slate furnishes very large slabs of different colours. There are some of a clear stone colour, very hard and very beautiful. A stone taken from it for a step to the communion table of Hillsborough church is 22 feet in length, and two in breadth. There are quarries of excellent slate, which are wrought to great advantage. At Crayleuth there is a black marble, exceedingly fine, and susceptible of a very high polish. There are mines of lead which were worked formerly, but are not worked now, at the Blundell estate at Dundrum, and also at Clonliffe, between Newtownards and Bangor. Copper ore has been said to have been found. There is coal too, but no encouragement to work it. This county contains, besides, ironstone, fuller's earth, soap-stone, and crystals. There are some mineral waters, both sulphuraceous and chalybeate; those near Ballinlough are most frequented.

Weights and measures. Wights and measures in this county, as in others, are various. In the neighbourhood of Guildford, the cwt. is 112 lb.; at Dromore it is in some cases 112 lb. and in others 120 lb. In the latter place the bushel is equal to 10 bushels, and the bushel to 32 quarters. The following is from Dubourdieu's Survey of Down: cwt. = 8 stone; stone = 14 lb.; ton = 20 cwt.; bushel = 32 quarters = 1 gallon; 1 hhd. = 12 Winchester bushels; hald = 10 Winch. bush. Oatmeal is sold by the cwt. of 120 lb. potatoes by the stone of 1 lb.; undressed and heelked flax by the stone of 16 lb.; beef and pork, when sold by the cwt., have it at 120 lb. tallow, per stone, of 15 lb.; hides, per cwt. of 120 lb. Oats are now only the grain sold in this country by measure.

Political divisions. Down contains, besides the lordship of Newry, eight baronies, viz. Upper Ivecagh, Lower Ivecagh, Kinealtry, Castleragh, Dufferin, Ardes, Lecale, and Mourne. In these there are sixty parishes. It is used to send in all 14 members to parliament. Since the union it returns only four, two for the county, one for Newry, and one for Downpatrick. The county freetholders are no fewer than 30,000. These elect, without a contest, whatever persons may be nominated by the Marquis of Downshire, who has divided and subdivided, and again divided his estate, so that it has become, what Mr Wakefield terms, a warren of freetholders. There are two regiments of militia, North and South Down.

The farmers and peasantry, with few exceptions, live in smoky huts, are extremely poor, and dirty and slovenly in their habits. A considerable improvement, however, in the modes of living has taken place of late years, and it is gradually advancing, though that advance must be slow, while proprietors continue to consider their tenants as mere engines of parliamentary and political ambition, and do not themselves lead the way to plans of amelioration. That part of the county which comprehends Hillsborough, Banbridge, Moyle, and round towards Newry, is inhabited by a middle class of opulent manufacturers, whose dwellings are neat and comfortable, and whose general circumstances exhibit evident symptoms of industry, civilization, and contentment.

According to Dr Beaufort, this county, which is all in the ecclesiastical province of Armagh, contains almost the whole of the bishopric of Dromore, viz. 22 parishes, having 23 churches, and extending over 143,700 Irish acres. The chapter is composed of a dean, precentor, chancellor, treasurer, archdeacon, and one prebendary. The lordship of Newry claims an exemption from Episcopal jurisdiction; and the proprietor of the lordship holds his own peculiar court, granting marriage licences, probates to wills, &c., under the old monkish seal. The bishop resides near the town of Dromore, not twenty miles distant from any part of the diocese; he has 23 parishes in his gift. In 1779, his revenue was about £2,200; it is now £4,500. The bishopric of Down and Connor were united in the year 1454. Of Down, only a small part of one parish is situated in the county of Antrim, all the rest, consisting of 38 parishes, having 35 churches, and covering 201,150 Irish acres, is contained within the county of Down. The chapter is composed of a dean, precentor, chancellor, archdeacon, and two prebendaries. Of Connor, there is only a part of one parish, extending to 37,000 Irish acres, in this county. In 1779, the bishop of Down and Connor had a revenue of £2,500; it now amounts to £5,000. He has in his gift 15 parishes in the diocese of Down and 38 in Connor. In the year 1790, the deanship of Down was worth only £2,500 per annum. It now lets for £3,700. Of the Protestants, who amount, according to the estimate of Mr Wakefield, to about one half of the population, the greatest part are Presbyterians. The Antiburgher Seceders have six congregations at the following places, Bally-Copland near Donaghadee, Newton Ards, Gilneekirk in the parish of Castle-removed, Hill Hall near Lisburn, Moira and Newry. There is also a considerable number of Quakers, and the Methodists are gaining ground. In some parishes there is not a family belonging to the established church. In some parishes also between Lisburn and Belfast, and along the southern shore of Belfast Bay, there is not a Catholic family, nor almost an individual who is not a Presbyterian. The people who inhabit the mountains, and the poorer classes in many other places, are of the Catholic persuasion.

Mr Byrne, a merchant in Dublin, has an estate here of £3,000 per annum, and is the only Catholic proprietor who possesses a qualification for being put on the grand jury. The yeomanry and higher ranks of this county, who have among them an Orange party, are very hostile to the claims of the Catholics, on whom they are too much accustomed to look as beings of an inferior order.

The county of Down is in length from north to south 51 English miles, and in breadth from east to west 39.5. Its area is 574 square miles, or 559,995 English acres. It contains 36,636 houses, which at 5½ to a family, give 201,408 inhabitants. At this rate, there will be about 15,28 acres to a house, nearly 42 houses to a square mile, and about 2.77 souls to the English acre. This is Dr Beaufort's statement. In 1751 the number of houses was 19,570, and in 1791, by a return of government, it was 38,351. Allowing, as Mr Dubourdieu does, 5½ persons for each house, the population, in the former year, would be 101,167, and in the latter, it would be 201,342. In the parish of Annahill he found, on enumeration, that there were on an average, 3½ to a house: There were 400 houses, and of course 2100 inhabitants, of whom a proportion of 6.5 or 318 were liable to serve in the militia. According to this estimate, he makes the population of the whole county to be 280,447. Mr Woods, a dissenting clergyman, gives the following return for the parish of Bangor: He says
that it contains 7000 Irish, or 11,340 English acres; that there are 6550 inhabitants, and that the annual births are 560. He adds, that this may be taken as a pretty fair average of the county. So that, at this rate, the population of the county would be 322,466; the number of individuals to an acre would be 1.78; and the annual births would amount to 17,777. This estimate is so different from the other, in which the number of houses is given on good authority, that it cannot be considered accurate. Indeed, it is next to impossible to say whether any one parish or small district can be taken as an average, in any one particular, of a whole county such as that of Down. In the town of Portaferry, there are 117 houses, and 525 inhabitants, which being only 4.5 to a family, makes the population of the county, at the rate of 38,351 houses, to be only 172,579. The return of the inspector-general of hearth money, in 1791, bears, that in the county of Down there were 38,551 houses, of which 31,147 had one hearth, 1974 had two, 483 had three, 235 had four, 148 had five, 89 had six, 42 had seven, 34 had eight, 13 had nine, 25 had ten, 67 had more than ten, and less than forty-four, 1118 were exempted as new, and 5977 as paupers.

See Beaufort's Memoir of a Map of Ireland; Newenham's View of the Natural, Political, and Commercial circumstances of Ireland; Dubourdieu's Survey of the County of Down; and Wakefield's Statistical and Political Account of Ireland. (r)

DOWNPATRICK, the chief town of the county of Down, in the province of Ulster, Ireland, is situated about six miles west of Strangford bay, and is encompassed by hills on the east and south, which confine the view to a small but pleasing extent. Near the town is a high hill, that commands an extensive prospect of the neighbouring country, and the river Koll, which is here seen advancing towards the town, under the noble hanging wood of Pontallagh.

It is a post, and borough town, and returns one member to the imperial parliament. It has a good linen market, and commands an extensive trade with the neighbouring country, which receives considerable advantage from its contiguity to the sea, having thereby an opportunity of exporting great quantities of potatoes and malt.

This town has long been celebrated as the burial place of St Patrick, and is reckoned one of the most ancient towns in Ireland, being noted in history before the arrival of St Patrick. Its present name signifies the mount of Patrick, which has been given to it from the Dun, or Ruth, which stands on the north-west of the town, the conical height of which is 60 feet, and the circumference 2100 feet; it is surrounded by three great ramparts, one of which is 30 feet high; and the whole circuit of the works is three quarters of a mile. This mount is supposed by some antiquaries to have been the chief residence of the kings of Ulalgh, or Down; others are of opinion that it was erected by the Danes, who made many predatory excursions to this coast during the 7th, 8th, and 9th centuries. In the neighbourhood of the town is the famous St Patrick's Well, commonly called Stateur, which the ignorant believe possesses many healing virtues, and at a certain season of the year it is much frequented by some of the superstitious Catholics, who perform their penance by going round it a number of times barefooted, or on their knees. The ancient abbey of Canons Regular stands near the town at the ascent of a hill, and was founded, it is said, by St Patrick, whose remains, tradition says, were interred here in A.D. 493; and in the year 1125, the bodies of saints Patrick, Columb, and Briged, were said to be discovered in this abbey, with the following epitaph written over them:

Hi treis in Duna tumulo tumdenter in uno, 
Brigida, Patricius, atQ. Columba Pru.

The cathedral stands at a small distance from the abbey, and was made the seat of a bishop by St Patrick. Near the abbey stood a round tower, about 70 feet high, which was probably used for a belfry; this tower was taken down some years ago, in order to enlarge the west end of the cathedral. The celebrated De Courcy, the first earl of Ulster, took possession of Downpatrick in the latter end of the 12th, and the Scots, under Edward Bruce, destroyed it in the beginning of the 14th century. The destruction of the cathedral of Down, in 1538, was one of the articles of impeachment against Leonard, Lord Gray, but it has been lately rebuilt: and it is worthy of remark, that the workmen, while repairing this church in 1789, discovered a stone coffin, the inscription of which was obliterated by the consuming hand of time, and found the bones of a skeleton firm, and most of them adhering together, in the same posture as when interred. On the legs appeared half boots, and the length of the skeleton was above seven feet.

The bishop's see is united to Connor, in the county of Antrim, and forms the bishopric of Down and Connor.

The town is tolerably large, containing four long streets, and many lanes. The number of inhabitants is about 5000. There are four houses of public worship, an established church, a Presbyterian meeting-house, a Roman Catholic Chapel, and a Methodist meeting-house. This being the assize town, it has a good county jail; there is also a county infirmary, and a small hospital, endowed by the De Clifford family for the support of the indigent, and the education of a few boys and girls. Its other public buildings are respectable; and the many antiquities of which it boasts are well deserving the attention of the curious. It is 20 miles south east of Belfast; 24 east north east of Newry; and 74 north by east from Dublin. West Long. 5° 39', North Lat. 54° 28'. (o)

The art of draining off the superabundant moisture from watery lands, so as to fit them for the operations of Agriculture, &c. We have already, under that article, detailed some of the modes of effecting this object; but as the subject constitutes one of the most valuable of rural improvements, and seems worthy of more minute detail, our intention, in the present article, is to give a more complete view of the principles on which the art depends, and their application to some of the most important cases of practice.

In all periods of our history, this subject appears to have attracted much of the attention of the legislature. Recitals of numerous enactments concerning drainage, may be seen in Dugdale's History of Embanking and Draining, and a particular account of the great national project for gaining the level of the fens in the east of England.

At a much earlier period, the Romans appear to have executed many works of the kind. The innings of Romney Marsh, the pattern for all our other reclaimed fens, is distinctly referred to that enterprising people. The foss-dyke in Lincoln, and many other ancient lobes and drains, were the work of their legions during the intervals of active war. The Frisian and Saxon colonists also, from the watery flats of the north of Germany, seem to have bestowed much labour in freeing the low grounds of England from the risk of inundation, to which vast tracts appear to have been liable in their natural state, and are even yet only barely out of the way of the water.* The feudal system and petty jurisdictions were particularly favourable to the management of works of this kind, and perhaps a proper equivalent has not yet been substituted for them in our modern policy. In England, however, particular codes of laws have been formed for this object, and commissions of sewers are numerous, and of great antiquity. Scotland, from its more uneven surface, and its frequent troubles, appears to have attended but little to this species of improvement; while Ireland, until of late, seems rather to have been retrograde; for if we may judge from the appearance of some of the bogs, the morasses of that kingdom have even extended since the introduction of agriculture. And though many vast tracts of that fertile island are either quaking bogs, or flats frequently covered with water, no commission of drainage was to be heard of in the kingdom, until lately, that, by authority of Parliament, a board of commissioners was formed to enquire into the nature and extent of the bogs in Ireland, and the practicability of improving them. They have already published two reports on the subject, containing much interesting matter, exhibiting the present state of the bogs in certain districts, and evincing clearly the practicability of converting these unprofitable wastes, at a small expense, into the state of arable and pasture land.

This example should stimulate the landholders of Scotland to institute similar enquiries respecting the waste lands of their country, the value of which is but little understood, though they are of much greater extent than those of the rest of Britain and Ireland; and there are political as well as moral reasons, which would make the legislature readily attend to, and second any well digested plan for their improvement.

By far the greater part of these wastes are covered with moss or peat of more or less depth; a beneficial provision which nature has made, to facilitate the operations of agriculture on soils that would otherwise be barren. All that is requisite, is to free them from superfluous water, which, in general, may be done at an expense comparatively trifling, and the application of other substances will then render them permanently productive. It is the business of the engineer to show how these operations may be facilitated; for, without regular and systematic management in great operations of this kind, there is always a loss of labour and time, and a diminution of effect.

Though this subject constitutes one of the most useful applications of the principles of hydraulics, it is surprising that so little attention has been paid to it by scientific men. Until lately in this intelligent and rapidly improving country, we had no such thing as any treatise on the art of draining, which, by laying down a few fixed principles, could enable the intelligent farmer to comprehend the cause of the evil that annoyed him, and to proceed at once in an unerring manner to its cure. All books of husbandry indeed profess to treat of draining, and, confessing its importance, proceed to give directions for performing it. But these books being, in general, written by men ignorant of hydraulic principles, contain only the results of rude experiments, directed by the random notions of farmers, groping about with enormous expence and labour for what a person of tolerable intelligence should have perceived at first. To what other cause can we ascribe the enormous ditches that are to be found in some quarters of these kingdoms; the multiplied hollow drains in others; the absurd directions or useless positions in which they are often laid, rendering them rather nuisances in a field than a benefit. Their consequent destruction and renewal has, in many instances, rendered the drainage of a field by far the most expensive operation connected with its cultivation. To this chiefly we must ascribe the immense tracts of watery land which yet lie waste throughout the country, the reclaiming of which would doubtless be the most profitable kind of agricultural undertaking that could be thought of.

The species of lands that admit of improvement by drainage, may be arranged as follows:

1st. Watery flats; comprehending fens, wet bottoms, marshes, (and even lakes and pools,) on which the surface water collects in wet seasons, by reason of the obstructed out fall, but which deliver the water from their surface as soon as a proper out fall is provided for them. The mode of relieving these may be named Surface draining.

2d. Morasses, or morses, as the bogs of Ireland, the moors of Holland and Saxony, which have commonly a sufficient fall, but on which a thick covering of vegetable matter has formed a soil retentive of water like a sponge; and with these also may be classed the deep

* The bogs and morses are most numerous on the western sides of these kingdoms. Does this arise from the eastern settlement of the Belgians and Gothic tribes, (an agricultural people), the nature of the soils, or the moisture of the Atlantic?
Draining.

retentive clays, or other poaching soils upon retentive bottoms, forming cold or wet lands, which, as far as drainage is concerned, are very similar to the former. These grounds are relieved by proper management of the subsoil; but, in treating of that division, we shall take a view of the distemperature of soils in general, as well those that suffer from drought as from abundant moisture.

3d, Springy grounds, such as bogs, quagmires, and quicksands, which arise from subjacent waters, and are relieved by draining the strata or bottom.

**Chap. I. Of Surface Draining.**

The principles upon which the drainage of low grounds depend are few and simple, and may be readily comprehended, by attending to the ramifications of rivers and streams, which are the natural drains of every country.

The lowest attainable outfall must first be discovered, and, if otherwise unobstructed, a main drain led up from it into the space to be unwatered. From this, there should be branches drawn into those which are not commanded by the main drain alone. The junctions with the main drain should be oblique, and pointing down the stream, that the influx of side waters may not tend to dam up those of the main. Into these branches, the fence drains of the fields are conducted in inclosed grounds, and the land is laid up in ridges and furrows, terminating in the boundary fence drain. Where the furrows are so situated as to run across a hollow, the waters of which they are not deep enough to discharge, the water furrow becomes necessary, and is drawn across them in the hollow ground, so that a general vantage may be gained to every part of the surface by an unobstructed fall, which is greatest at first, but may be gradually diminished, as the quantities of water increase, by uniting until the whole is discharged into the sea.

In searching for the lowest outfall, the spiral level must often be resorted to. There are, however, natural marks, by which the fall of the ground, and consequent direction of the flood waters, may be discovered in the flat countries. On examining the ditches, which become nearly dry in summer, it will be found that the leaves of the various aquatics, as the sisyrium, the water cress, the veronica, or brook lime, &c. invariably point down the fall, or in the direction to which the water passes. This observation is well known to practical drainers. It should always be kept in view, as the situation and direction of these plants will afford, in many cases, a more ready means of discovering the direction of the natural hollows than any other. During flood also, it is of consequence to mark the progress of the waters in their increase and diminution; and it is often advisable while they are stationary on the flats, to sound them, by inserting many pegs in the ground, so as to have their tops level with the water, by which means the heights and hollows are at once perceived by the different lengths of the pegs. This method is particularly convenient in laying out fields for irrigation by flat flooding.

With respect to the inclination or slope of drains, there are certain limits which must not be exceeded; the slope must be such as will at least permit the water to be carried off with sufficient rapidity to keep its channel clear, but not so fast as to injure it by acting on the sides or bottom. Mathematically speaking, the water should pass away with any the smallest inclination of channel, and even gradually accelerate in velocity.

But we know that in fact this tendency to accelerate is speedily destroyed by the friction and other obstructions in the channel, and these increase in proportion to the smallness of the quantity of water, so that great rivers are enabled to move with less declivity than is required for smaller streams. This has not been sufficiently attended to in the operations on the great English fans; for, instead of uniting the upper waters into one capacious river, they have been divided and led away to different outfalls, greatly to the injury of drainage.

**1.** Large and deep rivers run sufficiently swift with a fall of about 1 foot per mile, or . . . . 1 in 5000

**2.** Smaller rivers and brooks, with a fall of 2 feet per mile, or . . . . . 1 in 2500

**3.** Small brooks hardly keep an open course under a foot . . . . . 1 in 1200

**4.** Ditches and covered drains require at least 8 feet per mile . . . . . . 1 in 600

Furrows of ridges and filled drains, require much more.

The elevation of ridges measuring across, is, according to the soil, sometimes as high as . . . . 1 in 10

Where the ground is level, and there is not in the direction of the smaller drains a fall equal to the above, it may be given in the formation of the drain itself, by cutting it deep at the outfall, which is preferable to widening merely.

The limit to the increase of the fall depends on the cohesion of the stuff in which the drain is cut. Firm rocky bottoms may be supposed to bear water passing over them at any slope; but, independent of the old adage, that even the drop wears the stone, the boulders, &c. which are likely to be brought down by swift running streams, are, by their battering and rubbing, equal to the destruction of the hardest rocks; hence the beds of mountain torrents are cut to great depths even in strata, which appear able to withstand the effects of water for ever. The stream will sweep away the substances that form its channel until it leaves only those which have a gravity in proportion to their weight and figure, just sufficient to counterbalance the impulse which it communicates.

Now, the figure of the pebbles being supposed the same, the weight of larger masses is greater in proportion than the surface on which the water acts. Thus, a pebble of twice the diameter, has four times the surface, but eight times the weight. A table might therefore be formed, which would exhibit the nature of the bottoms of streams of any given velocity. Such a table the reader will find in the article Bridges in this work, being there intended to enable the builder to discover the velocity of a river by inspection of the bottom. But for the purposes of the drainer, it is to be wished that a similar connection could be shewn between the slope of the channel and the nature of the bottom which will admit of it. Now, from what has already been said, it will appear that this must mainly depend on the quantity of water which passes in the channel, since we perceive that there is required for good drainage a fall no less than eight times as great in the small drain than would be requisite for the large and deep river. The following Table may, nevertheless, be of some service; it is drawn from observation on somewhat larger quantities than usually require to be artificially conducted. The windings of the channel and depth of water will, however, make great variations from it.
DRAINING.

Table of the Fall or Slope, and Nature of the Bottom of Rivers and Streams.

The above Table is calculated for small rivers and brooks, as already observed. Rivers would require less, and small streamlets and drains more descent, to have the same velocity and description of channel. Straight and even channels also permit the water to flow much swifter than where it has, with the same slope, to wind round the different sinuosities of the natural bed, to pass over shoals, or through narrow, &c.

It may be observed, that a bottom of fibrous bog will bear a greater velocity than any loose earth or gravel. The intermingling of the fibres prevents them from being torn away. Accordingly, bog drains stand well, even upon great slopes, if they are not cut to the under stratum; but where that is the case, as it is generally found to be gravelly or sandy clay, the bottom swiftly gives way with the stream, and the drains choke, or blow up if they are hollow. It appears, therefore, not only advisable, but even highly necessary, to draw in sloping ground the drains across the slope, so as to be nearly on a level, since a fall of 1 in 630, the greatest that is absolutely necessary, is not sensibly very different from the horizontal. This disposition of the drains at the same time enables them to catch and collect the water as it descends through the soil down the slope, and prevents the same water from successively moistening lower and lower pieces of ground. This principle, however, is by no means generally understood by common farmers, among whom, in many cases, the only idea seems to be to carry away the water as fast as they can; and this they attempt by perpendicular parallel drains running down the slope, or by many branches collecting rapidly into one main down the hollows. They do not observe, that, in these cases, the water which falls on the field, unless it happens just to fall over one of the drains, is not in the smallest degree assisted in its passage away; for it will most probably descend through the loose arable soil, until it comes to the firm bottom, and then, as it can have no tendency to proceed sidewise into any of the drains, it must continue to trickle down the slope until it arrive at the bottom, in which situation a drain, though it may perhaps afford it a more unobstructed passage, can give no more fall than originally existed on the surface of the field. And hence, by the way, the propriety of rounding the ridges, that there may be a fall either way into the furrow from the crown; and upon which point it may be noted, that if the ridges are laid to come right down the slope, there can be very little use for furrows at all. In such cases, if it is not otherwise inconvenient, the furrows should be drawn obliquely across the slope, and, acting as catchwaters, would greatly diminish the number of hollows that would be requisite in an arable field. But more of this by and by.

The dimensions of open drains will chiefly depend on the nature of the soil, and quantity of water to be conveyed by them. The best form for facilitating the passage of the water, is to make the slope on each side 16 inches of base to a foot of perpendicular height; the breadth at bottom may be two-thirds of the depth of water, unless particular circumstances make it desirable to widen the channel so as to lower the surface. As to water-way, we have usually found the channels of rivers and streams running about two feet per second to contain about a square foot area of section for each hundred acres of drainage; but this will vary according to soil and climate. The usual size of the smaller ditches running through farms are three or four feet deep; but it is difficult to preserve the sides so steep. The drainage of every kind of ground is effectual, when the water is two feet within soil.

When the site is liable to be injured by foreign waters descending into it from the conterminous upper grounds, it is most advisable to cut them off at higher levels, before they descend into the flats, which, by this means, will have only their own waters to discharge. For that purpose, the catchwater drain must be resorted to, being drawn along the boundary of the upper grounds, so as to intercept the springs and streams flowing from them, until a convenient opportunity be found of discharging them into the receiving stream. It frequently happens that the water which is thus procured affords sufficient power to work hydraulic machinery, by which the neighbouring low lands may be freed from their proper waters, even when they have no natural outfall.

When the natural channel of the foreign waters lies through the site to be drained, as is the case with most rivers which overflow their low grounds, it is commonly necessary to confine them with embankments on either side, to prevent inundation in time of floods. The size and dimensions of the embankment must depend on the depth of water and reach of the waves to which it may be exposed. They must not only be high enough to keep out floods equal to the highest previously known, but also those which may occur after the space over which they used to spread has been diminished by the embankment. The floods of all rivers increase after embankment, since they are not only deprived thereby of a certain portion of channel, but also of those natural basins or reservoirs which used to receive the surplus waters of sudden swells, and of course regulate the supply to the lower reaches of the river.

Where long-continued floods keep the water for many days above the level of the neighbouring lands, it becomes advisable to puddle the embankment, or to carry up a wall or partition of impervious stuff in its middle, to prevent the transpiration of the waters. It is necessary that the puddle wall be inserted a foot or more under the original surface, as the waters in that case, having a greater space to pass through under the foundation cre there can rise again on the inside, are likely to choke up the several pores by their sillage more effectually.

The exterior slope of embankments should be at least twice the height. Even three times or upwards is advisable, when a reach of wave is to be resisted; but these slopes are seldom given, and hence the frequent failure of such structures.

The thickness at the top of an embankment may, the-
DRAINING.

Draining.
Embankments.

ritically speaking, be reduced to nothing; for, as it exceeds the height of the water, it has nothing to resist. But it is frequently used as a foot-path, and on the slightest banks cannot well be less than two feet. Six feet is a more advisable breadth for the banks of small rivers. The dikes of Holland are 18 ells at top, and are used as roads.

The inside slope of a bank is of less importance. About one foot of base to one of perpendicular is a pretty natural slope for most earth; but where faced with sods, it may be much steeper. Some advantage is thought to arise from making the face of the bank concave, as the settlement of the earth will be thereby lessened. We shall hereafter take an opportunity of giving the reader an investigation of the principles on which the form and thickness of dikes depend; it is a particular case of retaining Walls for supporting earth, running sand, or water. In the mean time, we offer him the following from Silberschlag Theorie des Fleuves, p. 72.

</table>

It is proper at all times to turf over the surface of an embankment; and should the exterior side be exposed to waves or rapid currents, additional precautions become necessary, as piles and planks of timber, or walls of masonry. In the latter case, it is highly useful to stop the open joints with heath and moss, which collect the silt, and lighten the dike; but in most situations where these embankments are made, stones and timber are of doubtful benefit, and the turf, being formed on sandy soil, has little adhesion.

The Dutch, their great masters in this art, were led, by many fatal accidents, to adopt a method of covering the front of their sea-dikes in particular, which may be called thatching them, with straw. The men employed for this purpose, kneel down on the bank, with their backs to the sea, and have beside them bundles of straw, of which they make ropes of an inch or two in thickness. When they have twisted about a foot of this, they press the middle into the sand of the dike, by means of a forked stick. The straw rope is then prolonged, and at the distance of about five or six inches it is pressed again into the dike; and thus they continue from the top of the dike to the bottom. Another rope is then worked in alongside of the first, and so on along the bank, the ropes being laid as regularly and close as in a beehive.

The quantity of straw consumed in this operation of thatching the dikes is, as may well be judged, very great; and magazines of it are everywhere kept in readiness, and regular overseers are in constant employ-

ment, to look after those structures on which Holland depends for existence. The grass springs up between the straw ropes, and after some time entirely conceals them; but they require frequent examination, and whenever they are rotten must be immediately renewed. A man covers about 800 feet per day.

Bulwarks of stone are frequently employed as a facing for dikes, but very injudiciously, being soon gulled out and thrown down. Courses of brick are employed with better effect, or a smooth covering of gravel, the slope of the bank being made so gentle as to admit the gravel to lie steadily. A very effectual facing is also made by fascines, or faggots of brushwood. Small osiers and aquatic brushwood planted along the foot of the slope, are a good defence against ice.

Where embankments are made on mossy soil, bog, or soft fen, they should have a base sufficiently wide between the ditches; as we have seen for want of this precaution, great lengths of dike overset or buried at once, by the ditches bursting in. In such cases, the soil, if possible, should be formed by attrition, or warping by alluvial silt; the counter-ditches cut shallow and at a good distance fromer, and if possible, they should be allowed to run for some time, so as in some degree, to drain the ground ere the embankment be completed. Should this be impracticable, a thin wall of turf between a double row of plank piling may do, until the interior area be dry, and firm enough to bear a stouter embankment.

The drainage of the embanked land is now to be provided for; it is conducted upon the principles already set forth. When an outfall sufficiently low can be found, a back drain runs along the inside of the embankment, until a proper opportunity occurs of discharging it. For that purpose it is sometimes necessary to convey the channel under the bed of the river itself, or some embanked branch of it, which is done by means of a pipe of stone or timber, called a fox, or culvert. The form of these will be described in the article INLAND NAVIGATION.

Where the embankment is only against floods or the tide, an opening is made through the bank itself to shut with a valve or floodgate against the exterior high waters, and which being opened when they have subsided, permits the internal waters to escape. In cases where this is not practicable, the waters must be lifted by artificial means over the bank.

Flood-gates are variously constructed: the simplest for our purpose is a valve or clapper, hanging by the top, and falling against the end of a pipe, or against a sluice frame; at other times sluices or paddles are made to slide up and down in a grooved frame; and in greater cases, butting gates are hung so as to shut against each other in the middle like folding doors, or to turn on a horizontal or vertical axis, by some of which a body of water is at times collected and discharged, so as to clear the mouth of the channel from obstruction. When this outfall is situated on a shifting beach, it is often advisable to protect it by a pier or jetty of piles, &c. and to remove the gravel or sand which this may accumulate as often as appears necessary, or to form a covered channel through the whole line of beach into deep water. Much may, however, be effected by the judicious position of the outfall, with respect to the currents, that it may not be warped up by the deposits from the river or sea, but rather swept clean. In dangerous cases, and exposed situations, a second valve is sometimes formed on the inside of the first; and by the admission of a certain
portion of water between them, the pressure on the exterior one is diminished. A good instance may be seen at Lossiemouth, in Morayshire, upon the great exit which has drained the Loch of Spey. Many other precautions are requisite for the security of these sluices; but we cannot particularise them here. When there is no natural outfall, the waters are lifted over the bank by machinery of various descriptions. The marsh-mill of the eastern fens, is a windmill, having a body of brick about 20 feet high. The axle of the sails, by two bevel wheels, communicate motion to an upright shaft, on the lower end of which a horizontal wheel moves another vertical wheel; on the outer end of the axis of this last, is a small water wheel, similar to that of an undershot mill, working in a case of wood or stone, and with a valve drain at the head; the little water wheel is thus driven against the fall, and throws up the water three or four feet, which permits its escape into the river.

When a fall of water can be had, a very simple marsh mill is formed by two water wheels, on one axle of which one is driven by the fall of water, and the other acts as usual, in lifting the water over the bank. The current of the river is sometimes used as the moving power: though this is not advisable, great benefit may, however, in many cases, be derived from the rise and fall of the tide. If the drains fall freely into the brook, the brook into the river, and that into the sea, nothing further need be wished for; but it often happens that one or other of these is so obstructed, as to cause injury to the lands above. The new channel, or operations for the amendment of the old, must be frequently executed on property which has no immediate prospect of advantage from the undertaking. Hence it becomes necessary to have legal authority for this purpose, and to form commissions of drainage, which, in order to do their business with effect, should have cognisance of the entire river or district, and of all the baron of land which is drained thereby; and they should have power to assess individuals or communities, according to the benefit received by the improvements which they effect.

Romney Marsh is governed by 24 jurors and a common bailiff. If any person should refuse or neglect to make necessary repairs, the bailiff does them at the oversight of the jurors, and charges double on the defaulter; the surplus goes to the fund for banks and repairs; the defaulter may be distrained for the same within the marsh.—35 Ed. III. Forty shillings per acre is the price paid for land taken for banks, ditches, and water gangs,—35 Ed. III. The bailiff and jurors were incorporated by Edward IV.

In a session of Sewers at Hfords, in Essex, 19th April 1639, an order is recited for raising L. 1706, to repair a breach in the banks at Bromley; and upon the neglect of certain persons to pay their quota, a lease for 41 years is made of several parcels of land belonging to them, unto others at a pepper corn rent.—Papers in Petty Bag Office.

Where any person, assessed by commissioners of sewers to any lot, and refuse or neglect to pay the land to be leased, or passed in fee simple, to recom pense the undertaker.—13 Eliz. cap. ix.

Chap. II. Of Subsoil Draining.

It is not enough to discharge useless waters from the surface of the land, we must also remove them from the plant bearing soil, if we wish it to produce any other than useless aquatics. In retentive bottoms, this is effected by drains in the subsoil or stratum, immediately beneath the action of the plough; but as a defect of moisture is equally injurious to agriculture, we shall, under this head, give a view of the distemperature of soils in general, with respect to moisture, and suggest what appears to us the most probable means of correction.

By the soil, we understand that stratum, which forming the upper covering of the land, affords support and nourishment to the various vegetables, and is stirred and exposed to the sun and air by the operations of agriculture. The thickness of this stratum, or depth of the soil, is very various; but in general it either already does, or by proper management may be made to extend to the depth of nine inches.

Soils vary greatly in quality, and are seldom composed of any single substance: but with respect to drainage, they may be all arranged into two classes, viz. the imperious, commonly called heavy or strong soils; and the porous, termed light or weak soils. Of the former kind are clay, or the substances combined with it, as clayey loams. Clayey gravels, &c. black peat earth also, before cultivation, is of this kind. Of the latter are sandy, gravelly, or other light loams, peat earth before cultivation, stone brush lands, &c.

The subsoil is the stratum which lies immediately beneath the former, and may be supposed to extend from nine inches, or the distance to which the operations of agriculture extend, to about 24 feet, or the depth to which drains are usually sunk, when intended to be covered and passed over with the plough. The limits of this however, like the former, are very variable; since, in many cases, uniformity in structure prevails to a great depth, while in others the soil lies immediately over rock, and may be said to possess no subsoil at all.

The influence of the weather, the agency of manures, and the residence of the various plants and animals that inhabit the soil, are confined to the upper stratum. The subsoil therefore chiefly demands attention, by its effects in regulating the supply of moisture. If excessively porous and dry, the soil above it is liable to be parched, and becomes unfit for the existence of plants. If porous and wet, the health of the plants above it is injured, or they give place to the ranker aquatics. If the subsoil be impervious, similar consequences take place, according to the weather; but if the subsoil be open to a sufficient depth, the water which filters through the soil, or which rises from the bottom, will be there carried off without injury to vegetation; while, on the other hand, a reservoir of moisture will be within reach of the roots, in the event of long continued droughts acting upon a light soil, and depriving the vegetables of their usual supply.

When there is land which nature has not already provided with this necessary stratum, it is the business of man to supply it. The substrata must be opened or closed as the case requires, until the water remain at a due distance from the vegetable mould. The distance depends on the quality of the subsoil and bottom; for loams will hold the water much higher than sand, and that again higher than gravel, owing to the greater capillary attraction of the smaller pores. The supply which is furnished or abstracted by the bottom, depends partly on its position, and partly on the specific composition of the strata.

The bottom or base of land is under the subsoil,comprehending every thing below the common operations of culture and drainage. It is the seat of springs, form-
Draining.

Draining. ed by waters derived from higher grounds; and of
swallows, which absorb or convey them off to lower.
These have, in many cases, an important effect on the
superincumbent soil, and their drainage is frequently
necessary for improving the land; but it requires a par-
ticular mode of management, which shall be described
under a succeeding head.

Like the soil and subsoil, we may also class the va-
rious kinds of bottom into the porous and impervious;
this being the most important distinction in the eye of
the drainer. But it may not be improper to be some-
what more particular in distinguishing the more re-
markable varieties of the strata of the earth, which will
give us a better idea of the qualities of the various soils
and subsoils, it being from the decomposition of the
former that these last are formed.
The crystallized mountain rocks, such as granite, &c.
seldom occur in situations fit for the labours of the agri-
culturist; it may be only observed, that having no fis-
sures, they are impervious to water. They decompose
into a sharp sand, which is one of the readiest conduc-
tors of water we have; and when covered by a clayey
or loamy soil, and well drained, form valuable lands,
producing great crops of potatoes and barley. The
chief granitic soils are in Cornwall, part of Leicester,
and Cumberland, in England; in Galloway, Aberdeen,
Ross, and much of the Highlands of Scotland; in Do-
negal, Galway, Wicklow, and Down, in Ireland. By
far the greater part are moors covered by fibrous moss.

The various kinds of slate rock are composed chiefly
of clay; and are therefore impermeable to water, ex-
cept in their cracks and fissures, which, near the sur-
fase of the earth, are numerous. The strata or plates
stand usually on edge, so that the water easily finds
its way down into them, and, splitting the rock by its hy-
drostatic pressure, works by degrees the surface into a
clayey loam. Under this the water sinks until directed
to the surface by closer strata; and then forms springs,
or watery land, according as it is in greater or less quantity. The ridges of the slate rocks running
parallel for great distances, form narrow hollows, which
are sometimes lakes, sometimes fibrous mosses, and can
only be drained with effect by cross-cutting the strata.
The ridges, on the other hand, are usually dry and fer-
tile. This kind of rock occupies a great extent of these
kingdoms, being found in Cornwall and Devon, most
of Wales, Lancaster, Cumberland, and Westmoreland.
The Highlands of Scotland, all the south and south-
east of Ireland, and in a band which runs from the
shore of Berwick across the channel to the banks of the
Shannon; as also in Derry, Donegal, and part of Mayo.
There are, however, many varieties, the best and hard-
est slate being nearly impervious to water, and keeping
the lands above them dry and sharp. The softer again,
or shales, imbibe water in considerable quantity, and,
parting with it slowly, keep the land above them con-
stantly moist and cold.

The sandstone rocks of every kind are more or less
porous, and transmit the water through their substance
like a filter. They are found in great abundance in
various parts of the kingdom. Often occupying the ri-
sing grounds, and usually of a reddish cast, the soil
produced from them is dry, and, though meagre, not
always unfertile. But the water passing through them
frequently acquires a mineral impregnation from iron
pyrites, which enables them to preserve vegetable mat-
ter from decay. From this cause we may account for
the numerous bogs or mosses which disfigure the base,
and banks of the sandstone hills, where water is fre-
quently oozing, and the bottoms of the deep sand dis-
tricts, from which it has not a ready passage. The
most effectual cure for it is draining to remove the
cause; and calcareous earth to free the water of its un-
sepctic property, by neutralizing the contained acids.

The greenstone, and green conglomerate or porphy-
ritic rocks, produce by their decomposition soils ex-
ceedingly fertile. The finer paste becomes a loam;
the larger pebbles form an open substratum: the rock
itself is generally close and retentive, though capable
of imbibing a considerable proportion into its substance.
The calcareous rocks are very various in texture.
The softer and granulous kinds, as the chalk in the
south and east of England. The oolite of Bath, the
cotesvold, &c. is of a porous and absorbent nature, and
imbibes the rain into its substance as fast as it falls.
The water descends, as in a filter, still more readily
than in sandstone rocks, until it come to an impervious
stratum, by which it is conducted into the sea, or thrown
out on the surface in the form of springs. The chalk
is only found to the eastward of a line from Dorchester
to Sunderland.
The harder kinds of chalk and limestone, though
closer in their texture in the individual specimen, are usu-
ally, in the great scale, divided by numerous chasms and
fissures, some of them opening into enormous caverns,
of which those in Derby, and in many parts of Ire-
land, are very striking instances. This kind of rock,
where uncovered by other soil, is consequently as free
a conductor of water as we know; even large subter-
naneous rivers sometimes pass through it. The most
striking example in these kingdoms is perhaps that of
Lough Mask, in the west of Ireland, where the waters
of a basin, of 250 square miles, pass for two miles un-
der ground into Lough Corrib. Many such basins are
alternately dry land and fresh water lake, according as
the supply is less or greater than can be conveyed
through the apophy, which forms their outlet. The
Cirknitz Sea in Austria is of this kind: See Cirnitz.
Such lakes are named Furloughs, i.e. Llandikes, in
Ireland, and are very common in Connaught. There
Furlough More, near Galway, covers an extent during
winter of several thousand acres.

Another sort of limestone is the magnesian, or water
Magnesian lime, occurring at shallow depths, and bedded in clay.
It is particularly remarkable for making lime, which
will set and harden under water; so that when applied
to land, it has just the opposite effect of common lime,
as far as drainage is concerned, binding and consolidat-
ing the soil, instead of opening it.
The limestone strata occupy a great extent of these
kingdoms, particularly in England and Ireland. One
great field runs from Berwick to Lancashire and Derby-
shire. The chalk also occupies most of the south and
east of England; and, in Ireland, the greater part of
Leinster and Connaght is a limestone country. There
are also many smaller tracts. There is but little lime-
stone in the north of Scotland, though it abounds in
the middle or lowland tracts, forming usually the ba-
son of the coal strata; as is likewise the case along the
Severn. The magnesian lime begins at Sunderland,
running southwards through the middle of England,
and turning off towards the Bristol Channel.
The coal strata are very various. The coal itself is
poresous. The chalk shale or till impervious, being
chiefly clay, and well adapted to cure the defects of the
deep sandy soils. The coal sandstones are usually some-
what argillaceous, and consequently not infertile. The
greatest tracts of coal country are from Bristol to Mer-
DRAINING.

Basalt. — Basalt, though an argillaceous rock, imbibes water into its substance, and parts with it slowly. It decomposes chiefly into an ochre earth, which is loose and porous on the hills; but in the deep bottoms, forms a strong loam upon clay. Antrim in Ireland, the Ochil and Campsie Hills, and some of the western isles, are the chief basaltic countries. The castle rock of Edinburgh, and neighbouring hills, may be also noticed. The basalt hills are noted for abounding in springs, which descend through their upright fissures, and are thrown out by the clay at their bottom.

Of the alluvial strata. Clay is an important member, and forms the chief material by which other strata are rendered impervious to water. When exposed, however, to continued drought, it shrinks, and cracks sometimes to great depths, thereby admitting water afterwards to penetrate it with comparative ease. Clay, therefore, is of itself not so thoroughly impervious, as when duly mixed with sand, gravel, or loam, which prevent it from shrinking to so great an extent.

Gravel. — Gravel of every description, from its open nature, is the most effectual of all conductors of water, at least when free from the admixture of earthy matter; for in this state it seems to aid the retentive nature of the loam, a mixture of it being frequently preferred for puddling hydraulic works. Where an open gravel is covered with strata of clay or earth, it is one of the most common causes of springs and watery land, the cure of which shall be treated of hereafter.

Sand. — Sand being formed of smaller particles than gravel, differs from it only by the slowness with which the water passes through, and the greater lightness which the capillary attraction makes it rise. In other respects, its properties are similar to those of the sandstone rocks already described.

Loam. — Loam varies according to the substances with which it is combined; but in general may be considered as retentive of moisture, at least after it is once thoroughly saturated and puddled, to use the technical phrase of drainers.

Moss-peat, or Bog, is of two kinds. The flow moss or red bog of Ireland, is a fibrous mass, composed of decayed vegetables of the moss kind; it retains water like a sponge, by capillary attraction, and after drainage, shrinks and compresses considerably. The other kind is that called black bog, in which the vegetable fibre of the mosses has undergone a certain degree of decomposition. This substance, though light, is totally impervious to water, and is frequently used in hydraulic operations for puddling, where good loamy earth or the like is not to be had. But after peat-peat moss has been broken up and pulverised by cultivation, it permits the water freely to percolate, insomuch that the upper parts of the ridges, especially when they are much raised, are apt to have the crops fail on them during the slight droughts of summer. Dried peat is quite impervious to water.

Having thus described the varieties of strata, and soils produced from them, we shall proceed to consider the effects of their various arrangement.

CLASS I. Impervious Soils. — Clay, or heavy Loam.

Case 1st. With Impervious Subsoil and Bottom.

Example. Deep strong clays, &c.—In this case, the rain water, after saturating the surface, being precluded from penetrating farther, can only get away by the slow process of evaporation. The soil is therefore continually moist and drenched during winter. Cattle passing over it poach the surface, and fill it with numerous cups or holes, from which the water cannot escape even though the surface have a considerable fall. The spring shoot of grass is late; the produce in wet summers is rank and coarse. On the other hand, in dry summers, the moisture is rapidly diminished; and as no supply can arise from the subsoil or bottom, the surface dries and hardens, cracking into gaps, which allow free admission to the sun and air, so as to scorch up almost every plant that is sown upon it.

In tillage, it is heavy and difficult to work, is cropped with uncertainty, and the semifluid clay, while the crop is young, is liable to close upon the roots of the plants, and suffocate them by cutting off the supply of air. The best account of this case, and means to be used for its cure, are those given by Dr Anderson; we shall give it in his own words. "These soils are usually in themselves naturally fertile when drained. It were to be wished that some less expensive mode of doing so were discovered than that practised in Essex, where they made covered drains of 2½ feet deep, running diagonally through the field at the distance of twenty feet from each other, or in every furrow. The wetness of this kind of land is not occasioned by springs, but originates entirely in the proper waters of the site, or what immediately falls upon it from the clouds. In copious rains, a part of the water finds its way along the surface into the furrows, if such have been made, and by which it will be carried off the field; but a considerable portion also sinks down into the porous soil on the tow, until it reach the solid bed of clay below, which never having been stirred or opened effectually, resists the passage of the water, so that it can penetrate downwards no farther. In consequence of this, it must force its way laterally towards the furrows through the upper mould; or if no furrows are provided to carry it off, it must gorge up the soil, and remain as in a basin, in which the superficial soil is mixed with the water in a thin paste, which remains of a soft consistency during wet weather, and in that state must be extremely injurious to the vegetation of plants.

When the dry weather returns, the sun and air will evaporate it, when the soaked paste, now deprived of its moisture, assumes a hard irony consistence, equally unfit for the sustenance of plants as in its moistened state. Such being the cause of this disease, the consequences may be easily removed. The opening of low drains running diagonally across the slope at a small distance from each other, if they can be kept open, will answer the same purpose nearly that the drawing of open water furrows would have done, and will doubtless mitigate the evil in proportion to their nearness to each other; but they must be very close together indeed if they remove it entirely; for still the soil must be drenched in the same manner as before, by the water forcing its way through it until it reaches the drain.

Now, as the rain water will sink perpendicularly through the soil until it meets with the solid clay before it attempts to seek a lateral direction, it must follow, that the lower part of the mould, or that nearest the clay, will be more drenched with water than those parts of it which lie at a greater distance above the clay. Of course, the deeper the soil the less will the surface mould be liable to be drenched with hurtful moisture; hence it follows, that if the soil shall be deepened to
such a degree as that the water, even during the greatest rains, shall not be forced to rise so high as to chill the roots of the plants which grow upon it, the remedy wished for will be effected.

It will be a matter of such great difficulty as at first sight it might appear; for as the soil sinks slowly downward through such a soil, that portion of rain which falls first continuing to sink regularly, if the soil be mellow, without stopping, goes gradually downward, making way for that which follows without being regained back upon it till it meets the bottom.

Hence, if we should suppose, for the sake of illustration, that the rain water sunk four inches downward in twenty-four hours, and that the rain continued without intermission for three days together, the water would have penetrated by that time to the depth of twelve inches, had it met with no interruption before the rain abated; but if the soil were not more than four inches deep, the water would have reached the bottom in twenty-four hours, after which it could go no farther, but the rain continuing to pour on more, the soil towards the bottom, by acquiring fresh additions of water every moment, is there soon reduced to the state of a semifluid paste; and as the water must rise higher and higher while the rain continues, more of the soil must be drenched by it until the whole becomes like a soft pap that is incapable of supporting the smallest animal.

Or, if the open furrows or under drains be near at hand, a part of the water will at last fall into these, and be carried off the field, after having wasted the surface mould in its passage, so as to carry off with it all the soluble parts of the manures it has met in its course.

But if the penetrable mould had extended to a greater depth, (say sixteen or twenty inches,) the water would not stop even when the rain abated, but continue to sink farther, till at last it would be all imbibed by the earth, without having reduced any part of it to the state of a pap, and even without the aid of any drain whatever. Thus would the mould, having never been reduced to the state of a paste, continue friable even when dry weather approached; and as the roots of plants growing on the soil would thus be invited to stretch to a greater depth, they would there find moisture sufficient to sustain them at a time, when, if they had been forced to spread abroad near the surface, for want of depth of soil, they must have perished for lack of moisture.

In this way the soil is rendered dry in moist weather, and moist in dry weather, to a degree that could not otherwise have been experienced; and as it has been already said, the water in its progress dissolves and carries with it a portion of the vegetable manures. This portion of manure, by the process above described, is all left in the soil, and of course tends to meliorate it instead of being carried off from it either by water furrows or the drains, which become indispensably necessary when the soil is thin, and which unavoidably reduces it to that poor hungry state, so frequently experienced under circumstances of the sort here described.

There are found in many counties of Great Britain and Ireland, immense tracts of poor, hungry, clayey soils, that are all reducible to the class of which we now treat. They have been denominated hungry, from the sudden disappearance of the effects of manures that have been need upon them; they are also called hide-bound, because of the hard stiffness, and miserable appearance of the surface. Few soils are in their present state more unproductive than these. Yet there are none, perhaps, which, under a judicious management, could be rendered more productive than many of them. It often happens that, over the whole surface of such soils, a thin crop of weakly rushes are produced while it is allowed to remain in grass, and fog or moss, which establishes itself there during the winter months, and is almost the only vegetable production, that gives a sickly verdure to the surface.

Upon examination, it will be found that, in all cases of this sort, the unloosened clay rises very near the surface; in consequence of which, the superficial mould which has been stirred by the plough, to a small depth only, being thinly spread over it, is subject to be drenched through its whole depth by every violent rain, the manures completely washed out, and the whole reduced to a pap over paste, that becomes hard like iron when the summer heat dissipates the moisture. Under these circumstances, whatever manures or cultivation are bestowed on it, are in a great measure thrown away, as they are seen to produce but very little effect, and these soils are therefore in a great measure abandoned as hopeless.

Many soils of this description, however, if opened to a greater depth, may be gradually brought into a state of greater productiveness. Indeed many of the most productive districts in this kingdom consist precisely of soils that were originally of this kind. When such soils are thus opened up, they are, for the reasons above assigned, more effectually drained than they could be by any other process. The manures that are, after this is done, worked into the soil, are never carried off from it, but gradually tend to ameliorate, and thus to render more tender and friable the bottom soil, so as in time to become deep, sound, and wholesome land, which is neither strongly affected by the varieties of drought nor of rain.

These effects, however, are not to be expected to be felt at first to their full extent. Some clays are so cohesive, that mere digging alone will not render them as permeable by water as could be wished. Before they can become sufficiently friable for that purpose to the highest degree, manures must have had time to operate upon them. For this reason, although the effect of deep digging and copious manuring will be at once sensibly felt, yet the melioration that will result from this process, will be going forward for many years to come; and by degrees will be coming nearer and nearer to that degree of productiveness for which the old lands of that description are so very remarkable.”

The means of deepening the soil require the consideration of various circumstances. Much will depend on the peculiar nature of the soil, of which there are many kinds belonging to this general class; and some will be more immediately benefited than others. In general, the surface mould, having been mellowed by frequent cultivation, should, by all means, be preserved at top, for the land in stiff clays where manure is not abundant, might be long in recovering the effects of trenching it down. It will be more advisable, after having turned over a large and deep furrow of the surface, to have men follow in the same furrow with strong and narrow spades to stir the ground without turning it to the top; or to follow the first plough by the minter, which is a plough without mould boards, calculated to stir the ground below without turning it to the top. This kind of trenching should be repeated when the soil is perceived to get bound below; and though it is by no means necessary to stir it up as often as the plough goes, yet it would be highly advisable to do so for strong soils during the autumn, that the land may be well prepared against the rains and frost of winter.
As to the modes of correcting these soils, it may be observed, that the friability and dryness is greatly promoted by liberal doses of lime, when it can be procured. Calcareous sand, which abounds on many of the shores of these kingdoms, is also a most valuable corrective for them; as, indeed, would be sand of any kind, and even dry peat mould or turf dust. Where no foreign substance is accessible, pairing and burning is still an excellent remedy, and should be resorted to without dread; though in many other soils it might be attended with injurious consequences. The clay, by this means, being baked, becomes a dry powder, permeable to water, which corrects the tenacity of the soil, while the rushes and other aquatic weeds are not only destroyed, but add a proportion of carbonaceous principle.

Though the above processes will, in all cases, operate a great improvement, yet it cannot be denied, that hollow draining may, at times, prove useful. The chief cause is the improper direction of the ridges; for if they run immediately down the slope and the top be flat, it is obvious, that whatever water falls upon the ridge will tend, after sinking through the mould, to pass forward on the clay in a direction down the slope, a course parallel to the furrow without falling into it. The consequence is, that the soil, especially in considerable declivities, may be as much drenched as if these furrows had not been made. To intercept that water, hollow drains are required, passing across the declivity; and care should be taken in constructing them, that the water may always have free admittance, while at the same time the materials may not be stirred, and of course the drain choked up by the plough: the best preventative for which is, to have the under soil so well opened that the water may pass into the drain laterally below the reach of the plough; for though the same end may be obtained by filling up the drain with porous matter, as gravel or turf dust, peat mould dried, yet it is difficult while the soil is under culture to prevent these from "puddling" up, or if not carried to the surface, to prevent the clay from caking over them; besides, such substances are not abundant in the clay countries. If the furrows were to be laid in the same direction as these drains, they would doubtless produce nearly the same benefit, and in many cases might be even more effectual than the hollow drains, since they are always open for the reception of the water. In other cases, where it may be inconvenient to plough in that direction, and in flat lands of retentive soil, as in most of the central counties of England and in Flanders, the general mode of drying the land is to lay it up in high and broad ridges of twenty to forty feet wide, with the centre or crown three or four feet higher than the furrows. The successful practice of the Flemings shows how effective this method is when well executed; for by attentively keeping the furrows perfectly free from water, the land is kept in a dry sound state, so that all kinds of crops succeed well. The frequent passage of the plough at a regular depth, forms as it were a polished surface under the stirred soil, parallel to the upper surface of the ridge. Upon that surface the water passes laterally into the furrows on either side, soaking through the stirred upper stratum; and by these furrows it is carried off the field. This is the true way in which the ridges and furrows act in the drainage of land, but it is not often sufficiently attended to. In many instances the furrows are not properly directed, or deep enough, or the ridges are too flat, by which means the water stagnates in the hollows, or lodges in the soil. This bad management has brought the method itself into discredit; so that in many places they have been levelling their ridges at great expense, without considering that this may, on clay soils, be very imprudent; for when the ridges are well rounded, not too high, with the furrows kept open and free from stagnant water, by means of well-directed cross water furrows, or gaas, as they are termed in the Cause of Gowrie, no mode appears better or simpler for draining land of a very retentive soil.

And here it may be observed, that since the most effectual way of draining these soils is by keeping them in constant cultivation, and to open and stir the subsoil, nothing can be more absurd than the policy so common in England, of prohibiting grass lands from being broken up by the plough. In soils of this kind, which compose a very great proportion of the grass lands of the kingdom, it is, in some measure, dooming them to perpetual sterility. Such land produces next to nothing in grass, while, by judicious culture properly persevered in, it becomes the most productive of all tillage. The reader will, we doubt not, see from hence the necessity of falls upon clayey and wet bottoms, which have been so much described by some agricultural writers.

Peat bog or moss may be compared to the clays in its raw state, or before cultivation, and should be drained in the same manner. Before its texture is broken, it will hold water like a dish. The facility of forming an open subsoil in peat is, however, vastly greater than in the clays; all that is required being to dig it, keeping the heath down: but on the other hand, the peat, when once dried, becomes like a piece of cork, and if wished to be productive, must be broken down and preserved in a certain degree of moisture. This is to be done by broad ridges and shallow furrows: the elevation of the middle of the ridge should be about ten inches. The drainage, however, though shallow, must be perfectly free, so that constant scouring becomes necessary when they are left open. The plants will thus be kept always within reach of a supply of moisture in dry weather, without which the crops might be blighted, and the upper peat earth, by exposure to the weather, cultivation, and manures, will be gradually converted into the most fertile black mould. The benefit of clay and earth mixed with peat, may easily be perceived from the tenor of this Section.

Deep drainage of mazes for agriculture, is therefore not only useless, but would be pernicious if effectual.

Case 2d. The Soil and Base as before—The Subsoil open.

Example. Clay loam upon gravel, or sand and clay bottom—bog or moss trenched, and cultivated upon black bog bottom.—The observations made on the last case will sufficiently inform the reader of the value of this kind of land, when the soil is of sufficient depth, and the subsoil sufficiently open to free the soil from collected moisture. Where the ground lies with a long descent, the water may possibly collect in the subsoil, towards the lower part, and pressing upwards against the soil, may soak through and injure it, forming a spongy clay soil. Whenever this appears, a drain must be formed across the slope, with a moderate descent, just above the part affected, by cutting down into the retentive bottom a few inches, and forming a channel there to receive the water as it collects, and convey it off to the open drains. If the slope be long, a succes-
Draining.

Drainage of these drains may be necessary; but in making them it will be proper to wait until the effect of the first be perceived before the others be opened. The principal case in which such a succession is requisite, is when the subsoil is sand, or a stratum through which the water passes with difficulty. In such cases, it is also frequently advisable to form a puddle wall across the subsoil, on the lower side of the hollow drain, for the more effectual security of the lower part of the field.

When the ditches in flat countries stand full of water, and gorge up the open subsoil, injurious effects are produced by the water lodging at the roots of the plants. The obvious remedy is to clear and lower the outfall, as already described in Surface-draining: The rule is, that the subsoil should be enabled to run completely dry, which will be sufficiently effected, if the water be kept at least two feet under the surface.

If such a fall cannot be had naturally, artificial means of drainage must be resorted to; and in these cases it may sometimes be necessary to form a puddle wall along the bounds through the subsoil, to keep off the influx of foreign waters, by a kind of embankment under ground.

Case 3d. The Soil close as before. The Subsoil and Bottom open.

Example. Deep loam or clay upon gravel, sand, or open rock.—This, if the soil is not only tenacious but deep, is a still more valuable kind than the last; care being taken to deepen the furrows so far as to communicate with the open substratum. Deep strong limestone lands are of this kind, and are of well known fertility.

But if the soil be thin, though sufficiently tenacious, it is apt to be parched, and to have its produce scorched in dry seasons.

The remedy is to deepen the soil, which, if no other mode is accessible, may be effected by gathering into high ridges or drills, or narrow beds, with alleys between, increasing thereby its thickness, though apparently lessening its extent.

Watering or irrigation is also found to be of peculiar value in this kind of soil; the remedy required being indeed the reverse of draining; and in order to retain the water in the subsoil, it might be advisable to form an artificial adherent bottom, similar to the Norfolk "pan," described below; or to introduce puddle walls of earth, at dead levels across the slope, which obliging the waters to descend lower before they could escape, might prolong their stay in the neighbourhood of the vegetables.

Class II. Open Soils.

Case 4th. The Subsoil and Base also open.

Though the due correction of open soils require an operation which is the reverse of drainage, it will not be irrelevant to our present subject to point out the most advisable modes of effecting it. Where the materials of these soils, though sufficiently open to prevent any surcharge of water, have yet such a due proportion of tenacious matter as to preserve the water from passing too rapidly away from the roots of the vegetables, the land is of a highly valuable kind. If this be not the case, and the soil be so open as to permit the water to flow quickly away through the porous substrata, the land is in a great measure useless. A few plants are, however, fitted to this kind of soil; and by encouraging their growth and decay, there will at length be formed from their exuviae a vegetable soil, which will in a great measure cure the defects of the original, and approximate it to

Case 5th. An open Subsoil on a retentive Bottom.

Though this kind of soil in its natural state resembles the former, it is more capable of remedy. Trenches, as above mentioned, must be cut across the fall of the
Draining.

ground through the subsoil unto the retentive bottom, and filled with retentive materials, as loamy earth, &c.
The furrows and ridges should also lie in that direction; and it would be proper in great declivities, to cultivate the soil in beds or terraces, the surface of which might be laid level. This practice is adopted in various mountain countries.

In these two last cases, where the country is flat and low, so that when the water stands in the ditches, the subsoil is gorged up with moisture, a disease of a different kind is produced. Land of this kind is among the most worthless that we know. In wet seasons, the rank aquatics take possession, and the site, if left to nature, would be speedily covered by moss, though, in dry seasons, the crops are scorched to the root by the sun and air.

The remedy, as in Case 2d, is to lower the outfall, by running drains in the subsoil. Care must be taken to prevent the sand from running into and choking them, and to lay them so as to preserve the bottom from injury.

If the outfall cannot easily be lowered, the soil should be laid in high beds, by excavating one part of it, and making up the other; thus acquiring a portion of dry land at the expense of a part of the surface.

Case 6th. The Subsoil and Bottom impervious. Sand, Gravel, or Loam, upon Clay. Light Moss upon black Peat.

This case, although possessing the same soil or cultivated stratum as the two last, differs greatly from them in quality. In wet seasons, the crop is liable to be chided, by the water lodging at the roots, and in the vegetative stratum, until carried off by evaporation. Aquatic weeds rise fast, and the soil is unfit to bear the tread of cattle, especially during winter. In dry seasons, the soil is scorched by evaporation, and can derive no moisture from below, so that the crops are stunted and blighted.

The remedy is to open the subsoil by trenching and following, as recommended in Case 1st, to which this has a great resemblance. Or the soil may be laid up in beds or high ridges, running across the slope with a gentle declivity, that the surplus water may be carried off in the furrows, while the soil is so far deepened, as to retain a supply of moisture in its pores for a longer period. This is the method usually practised in Ireland and in Flanders. Or hollow drains may be formed in the subsoil, running also across the slope, as is practised in Essex. Soil drains will answer well enough in such cases. If the lower soil be of good quality though retentive, a portion of the upper porous soil may be turned down by trenching.

In moss not thoroughly reclaimed, if the beds or ridges be high, the water passes too quickly away, especially when the land is in corn. It is better, therefore, in that kind of soil, to preserve the ridges pretty broad and flat, as a perch wide, and 10 inches high, but at the same time to prevent surcharge, by particular attention to the water furrow; and in all cases it must be observed, that every variety of soil requires a corresponding variation in the mode of management.

Case 7th. Subsoil retentive bottom open. The lack tea of Ireland, a hard Clayey Stratum below the Soil, covering open Gravel.

This case, in its natural state, resembles the last, but it admits of a ready cure; for, if the clayey stratum be pierced, the water passes immediately off by the bottom. But it is difficult to provide against drought. No remedy seems so obvious, as that of laying up the soil in beds so as to deepen it, while each alley may have holes pierced through the clayey stratum, so as to secure an effectual drainage during wet seasons, but be readily stopped up in case of drought. Or what would perhaps be still better, to trench up a portion of the gravel, to form a new subsoil over the first, and thus bring the case to No. 2. or 5.

Of the different kinds of Hollow Drains.

Before we proceed to the next division of our subject, we shall give a description of the different kinds of subsoil drains which are at present in use in different parts of these kingdoms.

Though open drains are perhaps the most eligible, for conveying the superabundant rain water from the surface where it falls, or for conveying the waters collected from the soil into the stream or river, they are by no means so advisable in drawing water from the subsoil, especially in lands under tillage. The substratum where the water issues is generally loose, and might slip into the open drain; and the tread of cattle is at all times injurious. Where the drain is intended to collect the water at its sides from the stratum in which it is formed, a certain depth of open materials is required for filling it, which is generally procured, by collecting the small stones in the field. These are termed "rumbling rivers" in some parts of Scotland. In Ireland, they are usually known by the name of French drains.

But where intended as an aqueduct or channel for water, collected from springs or other sources, it is advisable to form the drain hollow, by constructing a pipe or open channel along the bottom, and an absorbent stratum may be formed over it, so as to combine the advantages of both. In some cases, where drains are filled with straw or brushwood in firm earth, the drain at first is of the former, and, after these substances decay, becomes of the latter description.

In the eastern parts of England, where stone is scarce, and the wet bottoms were in most cases covered by coppices, it is likely that drains were first filled by putting three poles triangularly over each other in the bottom of the trench. Of late years brushwood has been much employed, and even straw trampled in or formed into ropes. Black thorns are found particularly durable; but wherever hard materials are easily procured, as pebbles or small stones, they are justly preferred for the formation of permanent drains.

The trench for the filled drain is formed by the plough or spade. In the former case two furrows are drawn, so as to leave a baulk between them of 15 inches wide; then with a strong double breasted plough made on purpose, that baulk is split, so as to leave a clean furrow 14 or 15 inches beneath the surface, or even by a second ploughing to the depth of 20 inches; it is then ready for the draining or land ditching spade, with which a narrow drain is dug of 15 inches deep. A scoop is also sometimes employed, for clearing out the loose materials in the bottom. These dimensions vary with the required depth and the plenty of materials.

When the drain is formed, it is next to be filled with such materials as the situation affords, the depth of which will of course be regulated by the supply of water. Fif-
DRAINING.

Hollow drains.

DRAINING. the largest and most open must be placed at bottom. Each faggot of brushwood, or bottle of straw of 140 to the lead, is sufficient for three perches of drain. Upon these materials a covering of some kind must be put, to prevent the earthy matter, with which the upper part of the trench is filled, from being washed down while yet loose into the porous part of the drain. Heth, straw, rushes, firn soil or clods, if such rise in making the trench, may be used for this purpose. Upon this covering, the loosenest and worst part of the excavated earth should be laid, and the finer mud reserved to occupy its place at the surface, and rounded up a little to allow for the shrinking. Plate CCXXXIII. Figs. 1, 2, show the form of this kind of drains. Fig. 1. is a drain filled with stones; Fig. 2. a clay drain filled with straw or brushwood.

Hollow or pipe drains are variously constructed. In districts where thin flat stones abound, and in cases where the subsoil is deep, and of a loose friable texture, square pipes of stone called goughs are formed at the bottom of the trench, by a wide flat stone as a bottom, a dry wall of splinters on the side, and a flat stone as a cover. The size of the pipe is about 6 inches in the clear. Similar drains are sometimes formed of bricks. Such drains are expensive, but effectual and durable. If the bottom be good, and declivity gentle, the sole or bottom stone may be omitted. See Fig. 3.

At other times, two flat stones are placed against the sides of the drain, meeting at bottom, and a third laid on them as a cover, so as to leave a hollow triangular channel for the water, liable to few accidents. See Fig. 4.

In Devonshire, where thin flat stones and rough pebbles are equally plentiful, it is common to form a channel, by coupling two flat stones triangulely, to meet at the top, and to fill in above with the pebbles. See Fig. 5.

Bricks are also formed for the purpose of hollow draining, and may in many cases be useful. These bricks are made of various shapes, but generally have a semicircular cavity for the water to flow in, and rest in stiff ground on the bottom, and in loose soils on each other, thereby forming a circular pipe or conduit. House tiles whelmed on pan tiles may also be used. These arch tiles may be made, when common bricks are at 1s. per thousand, at about 30s. per thousand without tax, and will lay a cavity of 6 inches by 5 of nearly 340 yards. Dried turf or peats have also been employed like bricks, in forming hollow drains in mossy soil. They might be cut by a grafting tool, somewhat in the shape of arched bricks; and even in the common shape, it is probable that they would last for a very long time in any kind of soil if previously well dried, while the facility of carriage would at the same time be of great advantage.

Drainage. Where a bottom of firm clay or stiff loam is situated beneath an open subsoil, very efficient drains may be made in the clay itself, by scooping out a groove of 5 or 6 inches square in the bottom of the trench, leaving a shoulder on each side. On these shoulders the upper sod is rested, with the grass side underneath; or sods are brought for the purpose from old grass lands. The excavated mould is then laid over the sod to fill up the trench. See Fig. 6. As the turf decays, a part of the cover falls down, and forms an arched roof to the pipe. Drains filled with straw, get into this shape by the decay of that substance. Another very simple kind of sod drain is formed, by means of a strong common plough, and may be found particularly useful on sheep pastures. A deep furrow is first drawn through the hollow parts where the water stagnates. A man follows with a spade, and piling off the loose soil from the lower side, so as to leave the sod or spawd about 3 inches thick, turns it back again into the furrow. By this means a triangular opening of 3 or 4 inches is formed, and will discharge a considerable quantity of water. An operation which, in case of need, may be easily repeated.

Hollow drains are also formed by billets of wood, set end on in the drain, and resting on either side alternately. The space left between them on the upper side is filled with brushwood, straw or rushes over that, and then the earth turned in. Aquatic weeds should be used, and laid when green. See Fig. 7.

Another method is to fix in a stick like a hoof, at the distance of every foot or so, and on these lay the brushwood longitudinally; or to lay some stout sticks across the shoulders of the drain, and cover this by spray, and the turf inverted. The greatest defect of these is, their being liable to be injured by the feet of cattle when ploughing.

When hollow drains are made in moss, it will be sufficient to cut down the fibrous turf to a proper depth, and then with the feather-edged peat-spade, or slave, to take out a groove in the bottom. This operation being performed in summer, the shoulders will dry, and become firm; and a part of the turf extracted being dried into peats, they may be placed over the groove, resting on the two shoulders, and the trench filled up with the broken stuff, which will be found to transmit the water freely. In the slitter countries, a slate may be laid in that way over the groove, and will be very durable. We have seen such drains running freely after thirty years, although the slope was considerable; a proof that fibrous peat moss, when kept from the sun and air, affords a good bottom for hollow drains.

In excavating such drains in moss, it is not necessary to dig open the whole length of the trench; for parts of the surface may be here and there left firm, and a pipe or sewer scooped out beneath them, to admit the water to pass along. These solid parts will be very useful as bridges, and soon becoming dry and tough, will, if gravelled over, admit even heavy carriages to pass on them. In this way, when the size of the drain makes it worthwhile, half of the cutting may be spared.

As peat, when once thoroughly dried, imbibes water again with great difficulty, and is so durable that as to be sometimes used in Holland for the foundations of houses, there is no doubt that broken peat would answer as well as stones for filling subsoil drains, and in many cases might even be preferable.

Various inventions have lately been proposed, for forming drains by machinery. Of these, the mole plough and draining wheel seem worthy of notice. The former consists of a bolt, or pin of iron, drawn horizontally at the depth of a foot or more. Beneath the surface, a thin coulter rises from the bolt or spade, and connects it with the beam, and is the only part which makes any mark on the surface. Even this disappears in a few days, leaving a bore of 34 inches in diameter, which is found to run well, and in cold retentive grass lands may be highly beneficial. The chief objection as to all other schemes of the kind, is the great retentive capacity required to draw it. A capstan and small anchor is sometimes employed for that purpose. The draining wheel has been already described. See Agriculture, Vol. 1. p. 329.
If the field has a considerable descent, care must be taken to have the drains nearly horizontal; for, if they have too quick a fall, they are apt to excavate and burst up. In such cases, as the drain only receives water from the upper side, it is advisable at times to puddle along the lower side, that the water may not, by running over through the subsoil, injure the lower part of the field.

When the hollow drain is carried through running sand, it is necessary to support the sides of the trench by boards and props, which are removed forward as the work proceeds. In making solid drains also, loose earth or sand is sometimes met with, in which cases the pipe must be lined with turf to prevent its choking, the loose earth being previously cut out to a sufficient width to admit of this.

The mouths of hollow drains being much frequented by cattle, should be formed with stone, or otherwise protected; and too many of them ought not to be run together, lest an obstruction in the main, cause an extensive mischief.

CHAP. III. Of Drying Spring Grounds by Draining the Strata.

Having now shown the principles by which the reclaiming of watery lands is effected, when the water lodges on the surface, or is injuriously stagnated in the soil, we proceed to the third division of our subject, in which we mean to consider those cases where the ground is hurt by the oozing of subterranean waters, or the flowing of springs, producing wet spotty land, bogs, and quagmires.

This subject is much more complicated than the other two: it constitutes one of the most beautiful, and perhaps the most important, applications of the doctrine of hydraulics; it is surprising, therefore, that it has been so little attended to by scientific men. Though many of them have written on the subject of springs, few have endeavoured to render their speculations so far useful, as to lay down a few principles for the benefit of the intelligent farmer, on a subject in which all are so much interested.

The first person in this country to whom we are indebted for a practical and intelligent treatise on the nature of boggy grounds, and the method of curing them, by relieving the subjacent waters, was Dr. James Anderson, in his Essays relating to Agriculture and Rural Affairs, printed in the year 1775. About the same time, Mr. Joseph Elkington had fallen upon the method of tapping subterraneous waters, by means of the auger, in the course of draining his farm in the county of Warwick. Mr. Elkington was, in consequence, much employed as a practical drainer; and his success was so great, that the Board of Agriculture, in the year 1795, proposed that a parliamentary reward should be given to him for his discovery. An account of his method was afterwards given by Mr. John Johnstone, and published by the Board, from which much useful practical information may be obtained.

Springs are formed, or have their origin in the different strata of the earth by the rain water which falls upon it, sinking into those which are of a porous nature, and descending until they meet with a bed of clay, close gravel, or impervious rock; upon this it either passes along the declivity of the bed, soaking through the porous matter which lies over it, or it collects, as in a reservoir, until it is emitted at some part of the surface of the ground, forming all the different phenomena of springs. Hence we see, that in countries of deep sand or gravel, without beds of clay to force the water to the surface, abundant springs are not to be met with; and again, the deep clay countries are equally destitute of spring water until we descend through the clay into a bed of sand or other open stratum, the only situation in which the water can flow in abundance, and in which it is only made to pass horizontally by a bed of clay, or other impervious matter opposing its further progress downwards. If this bed or floor of clay, instead of coming to the surface, should have its lower edge terminate in the sea, a deep lake, or the bank of a river, the water which has descended to it will find its way into these natural receptacles, without ever making its appearance on the surface of the land; and there can be very little doubt but that much of the water which falls on the dry land escapes in this way without being perceived.

But if, from the unevenness of the surface of the land, and the abruptness of the strata, the lower edge of the impervious bed should any where reach the surface, as is frequently the case on the sides of hills, in deep dingles, &c. the water, which was collected in the porous strata above, will there make its escape; and as a considerable time must be required for its passage through the obstructed interior channels, the intervals of drought will not always be sufficient to admit of the whole being delivered before a new supply comes again from above. In this manner, a frequent, or even continual, oozing of water may be formed; and if it be not confined to a narrow channel, but allowed to spread over the grounds below, plots of watery land will be formed, and in time covered with aquatic vegetables, which, by their decay, are converted into peat or bog.

This case has been denominated descending waters by some writers, and forms the first class of boggy ground arising from springs. Plate CCXXXIII. Fig. 8, represents a plan and section of a case of this kind. AB is a bed of deep clay, extending from the brook at A, back under the hill DE. CD is a bed of sand or open stratum covering the clay, and is covered in its turn by the different porous strata forming the hill or bank CDE. These strata imbibing the rain-water which falls on the hill, allow them to descend until they reach the line CD, where their further progress in that way is stopped by the bed of clay BA. They accordingly accumulate in the sand, until the increasing pressure forces them through the different pores and fissures in the horizontal direction DC, and they issue at Cc, the foot of the porous bank, in springs of pure water, which run forward in rills to the brook Ao, which, if an open channel is preserved for them, are not likely to do much injury to the farmer.

But it usually happens, that the edges of the porous strata EC, have been worn and broken down by the vicissitudes of weather or other causes, and their rubbish or detritus carried forward over the low ground CA, cc, forms a porous soil over the clay bottom. In this case, the water which issues at the springs Cc, instead of passing off in rills, soaks into the porous soil, and keeps it constantly drenched with wet, so as often to injure a great extent of ground below, especially if the subsoil be shallow or retentive, as is commonly the case with lands not ameliorated by cultivation. Many millions of acres in the upland countries of these kingdoms are still in this condition, their surface covered with peat moss or bog, which nevertheless might be drained at an expence inconceivably small.
The remedy is obvious and simple. Proceed to the upper line of wet ground, and examine if the springs there are flowing as abundantly as those below; if that be the case, you may conclude that the water is delivered by the "cropping out" of a bed of sand, gravel, or open rock, over a bed of clay or other close substance, at that place, and the lower patches are merely the overflow from thence; ascend to the level of a yard or so higher than the springs: you must then be in the open stratum.

Cut down a ditch, until you penetrate some way, (a foot or more,) into the solid bed or close substance; you will then perceive the water oozing from the soil above, and dropping into the trench which you have cut in the clay: continue the trench horizontally along the line of springs, making sure at all times to cross-cut the watery stratum: in this trench put a proper hollow drain or conduit, fit to convey the quantity of water, or if it be but short, you may fill it with stone; and it will not be unadvisable to build up a water-tight partition of the clay on the lower side, so as to prevent the water from overflowing the drain, and passing again into the soil below in wet seasons. Fill up the rest of the drain with stones or the porous soil, in the way already described. All the space must be put on the lower side.

From this catch-water drain there must be, in convenient places, tail drains to convey the water to the nearest brook. It is more advisable to make the fences of the fields answer this purpose; for as the slope is sometimes considerable, these drains must generally be left open, lest they should cut their beds, and burst.

But a drain may be made at the level of the catch-water, and brought out under cover until it reach the surface, along which it may then be conveyed as an open rill.

In carrying the catch-water drain along the line of springs, it may sometimes happen that springs appear above the level at which we are proceeding, in consequence either of a dislocation of the stratum, or by being in a small bay or glen, and that it would require very deep cutting to bring it into these springs on the same level. In such cases the drain may be carried across the bay, care being taken, if the soil through which it proceeds be porous, to prevent the water from escaping; for it is evident, that if we form a clear channel among the lower parts of the sand, that the water will be so far drawn off thereby as to drain all springs on a higher level that have their origin in the same stratum. But in case the bay or glen thus left out should become watery in moist seasons, a little horse-shoe drain should be run round it, upon the same principles, and delivering its waters into the general catch-water at each end. This little catch-water having a greater slope, might carry stuff into and choke the greater one, unless proper precautions be taken.

But the same measure will by no means answer in the event of our finding the sand stratum take a dip, or run out below the level of our catch-water. In such a case, it becomes necessary either to make an entirely separate catch-water round this lower tail, or to cut down across the porous bed into the solid floor, and bring up a regular puddle wall from thence to the surface.

When the upper waters are thus cut off, the grounds beneath deprived of the sources that supplied them with perpetual moisture, may be expected in a short time to become dry, as the water which they retain gradually passes away. In order to accelerate this operation, and at the same time to have an opportunity of cutting off any lower springs that may exist in the wet surface, it may be proper to draw other drains, parallel to and of the same description with the former, at some distance down the slope. And it must be evident, that where there are various strata of sand and clay alternating, each of them will produce, beneath it, similar effects, which must require to be obviated by the same mode of proceeding.

The declivity of the surface is frequently so little different from that of the strata, that a bed of sand, as DC, instead of ending abruptly, as in Fig. 8, may continue along the surface for a considerable extent before the inferior layer of clay crop out, or become distinguishable.

Thus, in Fig. 9, the bed of sandstone DC, which Fig. 9. comes from under the hill EDF, continues to run along the surface from F to C, and is not entirely lost until we find the clay at C rising or cropping out from beneath. The upper part of this stratum decomposed by the weather, forms a sandy soil throughout the space from F to C, which having an open stratum, will, in general, be friable and dry, and if covered with a rich loam, will form a peculiarly valuable soil, well fitted for the turnip husbandry. If the quality of water which sinks into this porous bed be tolerably uniform, and the bed of sand be deep, the moisture will never rise so high as to injure vegetation. But if it be so circumstanced that a considerable quantity of upper waters, during great rains, sink into and are absorbed by this bed of sand, then the difficulty of transmitting such a quantity will make the water rise higher in the soil, and though the upper parts, as at F, may be dry, the lower, towards C, will be gorged to the surface, and the water will ooze out of it in peering springs, forming a field there of damp sand, the most worthless that the farmer can possess.

In this case, the first subject of enquiry is, whether there be not at the tail of the sand an obstruction, such as the clay C, rising up and forming a kind of dam against the water lodged in the sand. If that be the case, let a drain be cut through the clay, and at the level of the bottom of the sand, or somewhat lower, as CB. Then along the tail of the sand form a drain CE, which giving free emission to the waters within, will allow them to sink to that level, so as not to be injurious. If this operation has not a sufficient effect, it must be owing to the pores of the sand bed not being sufficiently open to admit of the water passing with freedom. In that case, carry up the bleeding drain into the sand, giving it branches on either side, which, by enlarging the surface of emission, may make amends for the retentiveness of the soil.

But in such cases, it is often worthy of enquiry, whether it might not be better to cut off this load of upperwaters before they descend into and injure the field in question; and that, either by leading away the sources from which they are derived, or by forming a dam against them at the upper margin of the field so as to bring them to the surface, and in that way not only protect the lower field, but obtain a useful supply of water for other purposes. In this way (Fig. 9.) a ditch or trench is cut at G, being the uppermost part that appears damp in the wettest seasons, and is carried down through the whole depth of the sandy stratum into the solid clay below. If it is then formed into a drain in the usual way, the water from above will be com-
Draining.

Draining.

Drying of spring grounds.

completely intercepted; but, independent of the first cost, the expense of keeping such a drain in order would be very great, the depth in such a case being considerable. Another expedient that occurs, is to fill up the trench, thus formed, with a regular puddle wall, or partition of clay and gravel, loamy earth, or black raw pent moss, wrought with water to the surface, behind which the water, if properly intercepted, must rise as behind a dam; and when we have it within two or three feet of the surface, the drain may be forrowed in the usual way, so that the superfluous water is led to a proper outlet, and which in case of need is easily accessible; by this means the upper part of the field is so far drained, as to have an outlet two feet lower than before, and we acquire such a command of the water, that it may easily be kept up to its original level, while the lower parts, which were formerly of the nature of quicksand, and covered by morass, are entirely protected from upper waters, and have their proper waters drawn off by the bleeding drain c, as before. Where the overlying strata EF are of an impervious nature, the wetness of the sand may be, in a great measure, owing to the surface waters of a great extent of sloping ground descending over the surface EF, and being absorbed at F into the sand. In this case it is evident that these surface waters may be intercepted by a shallow drain, on the retentive soil above F, and led away to an outlet before they descend into the sand. It is equally evident, that we must be careful not to cut the sand in this drain, or, wherever that is unavoidable, that we line the trench, so as to prevent the water from sinking away; yet in this case especially if the uplands be in tillage, the drain will soon settle itself up, and be sufficiently retentive even over the sand.

The next case for consideration is, that where the stratum of sand, or other porous matter which conveys the water, dipping faster than the surface of the ground, does not crop out, or appear at the lower edge, but runs forward under the surface, and is covered by a layer of clay or other retentive substance.

Plate ccxxiii. Fig. 10. exhibits a case of this kind, where the watery stratum DC descending from the porous upland DKL, having no outlet at the point e, is covered by the retentive clay BEFG, extending back to H. In this situation, the water finding no outlet, will accumulate in the stratum DC, and be pent up as in a vessel, until it rise to the upper edge of the covering, and flow over as at H. Now, this level of the outlet being considerably higher than the surface of the covering of clay below, it is plain that there must be a strong pressure upwards against the bottom of the clay, in such a way, that, if a pipe was put down at G or E, to reach the sand, the water ought to rise in it to the level of the fountain H. If the bed of clay, as from C to F, be of sufficient depth and tenacity to resist this pressure, the soil on the surface will be no way incommoded; but if the covering be any where weak or thin, as from G to H, the head of water pressing against it will force some of the weaker places to give way, when it will burst out, and form a spring as at MM, and the water will immediately subside; and should this not be sufficient for the discharge of the whole in wet seasons, the water will again rise, so as to run also at other higher and higher openings, which after some dry weather will cease again, though the lower may still continue running. The upper level of the water will never subside so low as the spring MM, though it may remain very little above it, since at least some force will be required to press the water through the obstructions in the sand. From this cause, the ground from K to H, though of an absorbent nature, is frequently retained in a state of wetness, similar to that at CG, Fig. 9, on account of the moisture standing high in the subsoil, and, if left to nature, will be soon covered with moss. Again, where the texture of the clay covering is sufficiently strong to prevent springs from bursting out, yet the water will squeeze through all the pores and crannies, so as to saturate a small field of sprouting clay soil, producing only rashes, or other aquatic herbage, or brushwood from F to H. Where the depth of clay is so great as to prevent the oozing from being of much consequence, yet the water standing high in the subsoil, forms a field of cold, damp, clay land, as from M to F, and F to E, liable at the same time to be injured by the surface water from the springs above. In this situation, the cure is to form a drain in the neighbourhood of the lowest springs, and at such a level that the water which runs in it may be so much below them, as to leave the land dry. This ditch must be sunk down in various places, so as to tap the inferior watery stratum; upon doing which, the water lodged there will issue out in abundance, and flow along the drain; and having now found a lower outlet than the former springs by which it issued, these will quickly fall away and dry up; nay, if the stratum be of great extent, the same effect may extend to several boggy lands in the neighbourhood, and, to appearance altogether unconnected with the first. The height of the confined water being now diminished, the pressure upwards against the cover will cease, and this being the only cause of injury, a radical cure will be effected; but no hollow subsoil draining could have had this effect, although the land might be somewhat relieved thereby, in many instances, especially if the drains should any where touch the stratum of gravel or sand in which the water was contained; neither would any benefit be derived from a catchwater drain, made at H or K, in the last case; or even if we could sink down through the whole mass of sand, and bring up a puddle wall from the firm clay, would it be effectual, for such a dam exists, in fact, already in the covering of clay, BGH; and though we cut off most part of the supply thereby, the water in the bed of sand HC is not removed; the spring M which still delivers the little water that may insinuate itself, may be greatly weakened, or even cease to overflow, but the hydrostatic pressure against all the lower subsoil will still remain as before. We mention this the rather, that the inexperienced drainer may be on his guard, and not proceed to work until he is well assured of the nature of the case before him; for the mode of proceeding in one of these cases would be altogether useless in any of the others.

Having brought up the outfall, or tail drain BG, and formed the tap drain G G along the lower springs, our next operation is to open a communication with the watery stratum below, if that has not already been effected in digging the tap drain. Now, as a few passages will be sufficient to emit all the water, provided their area exceed that of all the springs, there can be no necessity for sinking all the tap drain to that depth. Small pits may be made at convenient distances, and, to prevent them from choking, they may be filled with stones, dried peat, or the like, through which the water will rise freely. But, in general, unless where the stratum to be pierced is very stony, and even in that case if it be deep, it is much easier, and less expensive, to make use of the boring auger, with which
holes are to be made at every few yards in the bottom, or on one side of the drain, down through the retentive covering, until the stratum below is tapped, and the water rises in the bore, and flows along the drain made in the upper clay. This instrument has been long employed in digging wells, and in mining for the purpose of searching for water, and drawing it off; but seems first to have been employed for the drainage of land by Mr Elington; though the principle upon which it is applied was first published, and the use of it suggested, by Dr Anderson. It is, without doubt, an instrument of great value to the farmer, both for this purpose, and for examining the various inferior strata of his lands, by which useful discoveries are often made. But its utility as a draining instrument is by no means so universal as at first it was proclaimed to be.

"The borer used in draining, is similar to that made use of in searching for coal, or other subterraneous minerals. The auger, shell, or whimble, as it is variously called, for excavating the earth and strata through which it passes, is from two and a half to three and a half inches in diameter. The hollow part, intended for the whimble used by carpenters, only the sides of the shell come closer to one another. The rods are made in separate pieces, of four feet each, which screw together to any length, one after another, as the depth of the hole requires. The size above the auger is about an inch square, unless at the joints, where, for the sake of strength, they are a quarter of an inch more. There is also a chisel and punch for screwing on, in going through hard gravel or metallic substances, to accelerate the passage of the auger, which could not otherwise perforate such hard bodies. The punch is often used when the auger is not applied to prick or open the sand or gravel, and give a more easy issue to the water. The chisel is an inch and a half or two inches broad at the point, and made very sharp, for cutting stone; and the punch an inch square, and sharpened also. There is a shifting handle of wood, that is fastened with two iron wedges, affixed to it for the purpose of turning round the rods in boring; and also two iron keys, for screwing and unscrewing the rods, and for assisting the handle when the soil is stiff, and more than two men required to turn it.

The manner of boring and this. In working it, two men, or rather three, are necessary; two stand above, on either side of the drain, who turn it round by means of the wooden handle, and when the auger is full they draw it out; and the man in the bottom of the trench clears out the earth, assists in pulling it out, and directing it into the hole; and who can also assist in turning with the iron handle or key, when the depth and length of the rods require it. The workmen should be cautious not to go deeper at a time than the length of the shell, otherwise it is difficult to pull it out. Two or four flat boards, with a hole in the side of one of them, and laid across the drain, are useful for directing the rods, and for the men to stand on."

In boring or forming pits for tap-drains, it is not necessary to put them down in the quagmire; for that can seldom be done with effect, the stuff closing upon them so speedily. It is better to have them in the firm ground, as near as possible, especially at the commencement. After the water has been tapped by these, the quaggy ground will subside, and get firm; enabling us to prolong the drain, if need be, and to sink new pits or bores, in case the stratum containing the water should be interrupted. The most convenient place, without doubt, is that where the stratum approaches nearest to the drain. The bore C, which is put down near the tail of the sand, is not more useful than the bore G at the same level; while a bore at g, which passes the tail of the sand, can be of no benefit whatever. In general, immediately over the watery bed there is a stratum of tight clay mixed with stones, of great firmness, under three or four feet of quaggy ground; this has often deceived the inexperienced drainer, by leading him to think he had arrived at a sound bottom. This is a good situation for laying the conduit or sough of the drain, if the level of the outlet admits of it; but it must be pierced by the borer, or pick and spade, without regarding the trivial springs that appear therein, until the reservoir be arrived at. By a careful examination of the adjoining ground, it is sometimes possible to say at what depth this may be found; but, in general, the rule is, to go down till the water rise immediately on withdrawing the auger. Mr Elington has bored thirty feet before the water flowed plentifully, but from this to fifty feet is more usual.

The improvement of this general scheme that often occurs in this kind of draining, and, at the same time, show how the same principles may be applied to other cases, and especially the digging of wells.

DC is a stratum of sand, resting on a bed of clay or solid rock, and extending under the hill L: it only basons or crops in the level valley from E to K, where it forms the bottom of a peat bog or moss, which has risen over it, on account of the valley having little declivity, so that water stands constantly in the sandy subsoil. BE is a bed of clay lying over the sand, and likewise running under the hill; beyond which it crops out at E. This bed of clay in the vale, from C to F, is but thin, so that there it forms a bottom of spouting clay soil, with springs and quagmires, owing to the pressure of the water in the sand bed below. The hill L is composed of gravel and sand; but, on the right side at F, this is overlapped by a thick cover of clay to the summit: on the left side also, at H, there is a cover of clay, which is much thinner, and does not extend to the summit: it abounds in springs, forming a bank of spouting clay soil with rushes. Each of these covers of clay unite with the bed BE at the foot of the hill, where a field of cold clay land is found on either side.

Now, the improvement of this general scheme is shown by the proprietor on the left side, who proposes to drain the moss KE by bleeding the sand; for this purpose, he leads up the main drain EC along the tail of the sand, where it meets the clay. He finds it necessary to sink it only by little and little, so that the sand may have time to drain and get firm, otherwise the sides run in upon him: and that he must clear the whole length of the drain to the outlet, before sinking any part lower than another; for after getting down an inch or two, the sand appears as fluid as water. In this operation he succeeds to a certain degree; and it is perceived, that the run of water from the valley, by the drain E, is greater than it had ever been before; and at some time, the quaggy bottom on the right of the hill has been somewhat benefited, and the springs at G give rather less water. The reason is obvious: a part of the supply is diverted, and the fountain-head lowered. Were he to persevere until he came to the bottom of the sand, the land at G would be drained, for it is on a higher level; but this proprietor has no interest in so doing.

He next proposes to find water at K, in the morass,
Draining.

Plate cccxxiii.

Draining.

PLATE cccxxxii.

For which he sinks readily in the sand to the level of the drain E. Below that is a quicksand, which can only be excavated by dredging under water. His next operation is to drain the springy bank below H, and, at the same time, to get water at a high level, he makes a tap drain H/; and bores in the bottom, until he cuts the open gravel of LHF, which furnishes a supply, and relieves his ground.

Suppose now the proprietor on the right wishing, in like manner, for a supply of water, makes a tap drain on his side, along the hill, as at F, but somewhat lower than the level of H, and bores into the under stratum; the water of the hill LHF will now flow away at F, and the drain H/ can be dry; but the land round H will be somewhat better drained than before. Suppose the proprietor at H still wanting a supply there, should bore down through the stratum of clay EB, and, into the sand DC; instead of raising any water by that means, the whole supply of HLF will now run down through the bores at H, into the sand DC, and pass away by the drain Ee; so that the ditch E/f will in its turn be dry. Nevertheless a well or pump at F will always find water in the tail of the basin HLF; and if the bore at H be below the level of the drain E, the supply may even be more permanent than before, since it communicates with the great bed DC.

Lastly, suppose that the wet bottom on the right hand is to be drained; for which purpose the tap drain Gg is laid out, and bores sunk into the sand DC. The water will now rise up from the sand, and relieve the quaggy clay above; the springs in the bottom will cease, and, what may appear still more remarkable, the main drain Ee beyond the hill will ebb dry, and the quicksand around will become firm and dry, as now as the level AGB of the tap drain. The well at K may now be sunk without difficulty; but no water will be found until we arrive at the clay, (above the level before mentioned,) and even then only by cutting a reservoir in the clay, to receive a part of the waters which trickle along its surface through the bottom of the sand. No overflowing well can now be made in that situation, even should there be strata containing water to a higher level below, which might be bored into, unless a close stearing or casing be carried up through the sand bed DC, to prevent its ebbing away by that channel through the drain G; but, before tapping at G, if we had inserted a bore at m, which is below the level of E, we would have had an overflowing well on the top of a hill; and again, if the stratum of clay at H were not yet cut through, we would have at the same time another overflowing spring at F, which would appear to be the hill from which the fountain at m was derived. We have seen instances of this kind in natural springs. It is worthy of remark, that the proprietor on the right side dried likewise the grounds on the left, in the act of draining his own; and he could not avoid doing so. Similar effects take place frequently in the drainage of mines; and when these are level free, they may be frequently applied to the purpose of draining the lands above, by boring down at H, or boring upwards from the mine. But where the mine is drained by artificial means, as pumps or the like, it becomes of the greatest consequence to cut off and remove all supplies of water that may enter from above.

Suppose, for example, that DC were a bed of coal, or other mineral, drained artificially at K, and that a shaft were to be sunk at H, it would be necessary to pass through the open stratum in the hill LHF; if this were a quicksand, abundant in water, it might be very difficult to be effected; and it would be necessary to introduce piece after piece of curb timber around the shaft, to prevent the sand from running. Even if we should succeed in getting down, the water would descend through these timbers abundantly, as to greatly damage the water on the engine at K, and might even drown the mine. The remedy, in that case, is to surround the leaky part of the shaft H with an inner casing of timber, and a puddle wall of clay, &c. behind it, and to unite this puddle wall with the beds of clay both above and below. The mine being then relieved of foreign water, will be restored to its original state, and will come again under the power of the engine. But suppose the bed EB not to be so completely retentive, but that water may penetrate through it when the lower beds are laid dry, especially if it be pressed by a great force, as the water accumulating in the hill LHF, then it may be still possible to relieve it from that pressure, by tapping; for example, at H or F, so as to lower the head of water in the reservoir, which will not then be able to penetrate through the bed EB, or, at least, not so abundantly, and the engine at K will be greatly relieved. Similar effects will also be produced; by having a catch-water dam, or puddle wall, to lead off the water, which would otherwise be absorbed on the upper side of K, towards the crop of the strata, as described in Figs. 8. and 9. A leaky stratum may be covered or lined with puddle, and secured in a similar way. The writer of this article has puddled the fissures of a leaking rock, and sunk shafts into it, although situated under the water of an extensive lake.

Suppose again, that the proprietor on the right hand at B intends to work his part of the bed of coal, and to drain with engines by the shafts G or m. But that the proprietor A, who will be equally, or more benefited, and whose engine at K will thereby become unnecessary, refuses to assist him. Then B, having no other resource, places a powerful engine at G or m, and sinks to the coal; but he takes the precaution, after driving his engine level along the coal as low as he can reach, to make up the lower side of it with a puddle wall of clay, &c. In like manner, he cuts out the coal along all the boundary of his property towards the basin, and replaces the excavation by water-tight materials, so that all the water which formerly flowed in upon him from the basin of the strata is now puddled off; and he finds the drainage of the remainder can be effected by much less power, than was necessary for his first engine at G. While the proprietor A, whose coal at first was laid level free, is now perhaps worse off than before, since he is deprived of the benefit of springs, that may have flowed at G, below the level of part of his coal. Should there be absorbent strata in that direction, and above his level, he will be benefited by the puddling. A case of this kind occurred some time ago near Edinburgh, and occasioned much litigation. The beds of coal, and other minerals, are frequently traversed by natural partitions of water-tight matter, which are of great benefit in the drainage of the mines. It is surprising how thin the partitions are, which resist great depths of water in this way; and which, when they are incautiously broken through, are productive of great difficulty, and even danger; so that it is advisable, in all dubious cases, to make constant use of the boring iron, to discover them, as the hole which is thereby made may be easily stopped up in case of need.

Puddling is also used in the digging of wells, to keep out salt or mineral springs, which may flow into the
DRAINING.

Before the stratum containing wholesome water is reached; and it is also used in mining for protection against a stratum, which emits hydrogen or inflammable air. A remarkable instance of the former is related in the Philosophical Transactions, vol. lxiv. where an account is given of sinking a well at Sheerness. When similar circumstances occur in boring for water, the remedy is to introduce a pipe of wood or metal into the bore, which admits the water only at the lower end. Nearly the same advantage is sometimes obtained by excavating the hole a little wider in such a stratum, and pressing in clay, which the water will keep from being displaced. If the water in the spring, which is formed at G, were confined by a surrounding wall, it might be made to rise to the level of the original outlet at E; and a pipe might be laid from thence to the top of the bank at m, so as to deliver water without sinking a shaft there, or boring for it; for in neither of these cases would it rise higher than the level of G, if previously tapped there. Or the same water, if abundant, may be applied to the working of machinery, when a fall is in this way obtained for it. A very pretty instance of this occurs at Cong, in the west of Ireland, where the waters of the great Lough Mask, issuing in a magnificent fall, are dammed up by a wall, and immediately applied to the turning of mills.

The effect of the bore at H, in this Figure, shows how wet grounds may sometimes be drained, by letting down the water into an open stratum below them. The most useful case of this kind, is that of a land-locked bottom, into which the cutting of a main drain through the bank would be attended with very great expense.

Plate CXXXIII. Fig. 12, shows a case of this kind, where the large bottom, EGF, is shut in by the high ground L and M. These grounds, though composed of open rock or gravel, have a cover of clay at least on the side next the hollow, through which the water cannot descend, thereby forming a lake, or at least it descends very slowly, so that the bottom is frequently under water, by which means it is converted into a peat-bog or moss, and gradually fills up with this vegetable matter, until by this means, and the water which it absorbs, the surface swells so far, as to throw the superficial water off by means of the brook AB; while the middle becomes a deep hollering bog, inaccessible to man or beast, except when the sun and wind, by evaporating part of the moisture, have formed a thin crust on the surface.

The obvious remedy is, to lower the outlet, or drive a deep cut, or an underground tunnel, through the ground M, into the lower part of the basin. But this may be too expensive an operation. Examine whether there is not an open stratum below the basin of clay, or one which, if it should be glutted with water, may yet be tapped somewhere, as at B; then, in that case, open a main drain through the middle of the bog, with cross and surface drains, to intercept and deliver the water into the main. In this main there must be smaller holes sunk down into the open stratum; these will swallow up and carry off the water. Care must be taken to prevent the moss and clay from finding its way into the swallow holes, which would soon choke them. For this purpose, a filter of stones, or the like, must be placed round them; or a pipe made of wood, slates, &c to rise something above the bottom of the main drain, which thus becomes a cess-pool. And that they may be as little as possible loaded with foreign waters, form a catch-water round all the bottom in the retentive cover, which may deliver the surface water of the surrounding grounds, by the original lowest outlet gh. The surface of the bog will subside; but as all the drains will subside with it, and the main drain most, they will still continue effective. It is quite unnecessary to cut such drains down to the clay bottom.

One large pit or swallow-hole in the lowest part, would answer equally well for a bog of limited extent, if it could be carried down to the open stratum; and that it would be less liable to choke. The main drain may be led into it; but the drainer must not expect the peat-bog to be bled by such a pit alone, without the assistance of surface drains. Swallow-holes are common enough in the great bogs of Ireland, many of them of great depth and magnitude, usually in limestone rock, and they have obviously been formed after the bog had accumulated; yet they produce very little effect, even very near them, though they may sometimes save expense in cutting drains.

Dr Nugent, in his Travels in Germany, 1766, after describing the mode of surface-draining the moors or turf-grounds, mentions this "practice as of good effect, and chiefly if the moors are not too wet and marshy."

"It is the nature of moors in general, that beneath the turf or moss there is a loam, which hinders the moisture from penetrating; and this, indeed, is what makes the marsh, and causes the luxuriant growth of the turf or moss; but this loam or clay is only a stratum, and far from being of an immense depth. Under it is generally a sand, or some other stony or loose soil."

Here reason informs us, that a middling morass may be drained by perforating the clay, and thus make way for the moisture to penetrate. In order to effect this, a pit is dug in the deepest part of the moor, till they come below the obstructing clay, and meet with such a spongy stratum, as in all appearance will be sufficient to imbibe the moisture of the marsh above. Into this pit the ebbing of the morass is conveyed through a trench, and both the trench and pit are filled up after the first drain with large broad stones, setting them edgewise, so as to leave interstices for the water; then such stones are laid over breadthwise, and these covered with loose earth, like that on the surface. When no such stones are to be had, strong piles are rammed down the sides of the trench, and broad boards laid across, and these are covered with earth to a height fit for culture.

"This is a matter of no great expence, the pit being as near the morass as the water will admit, and the trenches but short. Then they have a drain unperceived, which leaves the surface of the trenches for the plough; and in middling marshes, especially in such moors as are only wet and damp, this method, though sometimes slow, never fails to take effect; and many tracts are thereby made serviceable to the farmer and grazier."

The same practice is known in England. "If a pit is sunk 20 or 30 feet deep in the middle of a field, through the Hertfordshire red flinty and impervious clay into the chalk below, when the usual quantity of chalk is taken out, the pit shaft is filled up with the flints taken out of the chalk and clay, and the top drainage of this part of the field much shortened for ever afterwards, by making principal drains from the part of the field above the level of the top of the pit terminate therein,
and the superabundant moisture will escape through
the flints in the pit shaft to the chalk below; and if a
drain is carried into a limestone quarry, it is seldom
p. 66.

A similar practice is recorded as common in Flint-
shire, where the well is left open, and railed round
against cattle; and the reporter observes, that though
in this and many other instances, the top water esca-
ped through the pervious substratum, the effect might
have been directly the contrary; he therefore recom-
mands the use of boring-rods, as the hole made by
them is easily stopped up.

The employment of boring-rods for this purpose is
mentioned in the Report of Roxburgh, &c.

We may here observe, that the filling up of these
pits with roots of trees, stones, &c. recommended
by some authors, is very injudicious. After incurring
the expense of making them, they ought if possible to
be kept clear; and the filters necessary for that purpose
(of which the cess-pool already mentioned is perhaps
the best) preserved in a situation to be easily accessible.
The sediment may be removed now and then for ma-
ture, and that in the pit taken out by a boring dregge;
whereas the stones and roots could only be cleared out,
by drawing off the water, with great trouble and ex-
 pense. We have seen a bottom of this kind drained,
by cutting horizontally into the open stratum, as GO,
instead of sinking a shaft to it; and perhaps the best
way is to sink a deep cut or shaft, EK, near the edge,
until the gravel, &c., be cut at a proper level; and from
the bottom of this to carry a dregge horizontally towards
the bog, as the work in this way will be dry during
the execution.

The next case for our notice, is that of grounds lying
on the crop or basset of the strata, instead of being to-
wards the dip; the most remarkable effect of which is
the alternate beds of wet and dry soil thereby produ-
ced.

Fig. 13. explains this situation, shewing a hollow in
which there are alternate beds of sand and clay, or the
like, dipping into the hill. This may be considered as
the dry side of the hill, and will, in general, be found
so, provided the different beds of sand have any lower
outlet; for of course all the water they imbibe will run
off by that; but if not, then the water, falling from
the summit O, will sink into the bed of sand KML,1,
and fill it up like a dish, until it run over the lip at
K; then, after keeping the surface K wet by soaking
along the soil, it will subside into the land HFGE. We
may suppose a little of the soil worn down from KH,
to form a cover at the lower edge, of HE forming a
spouting clay. The water running over this, and wetting
the clay bed ED, subsides into the sand DB, which, be-
ing nearly level at top, it completely fills.

Lead up a drain across the different strata at the
lowest place, notching it pretty deep into the upper edge
of the clay, then the water running off from the sands
at lower levels, will not afterwards overflow. If it is ne-
necessary, carry a catch-water k k along the tail of the up-
per sand, which, cutting off the first supply, may perhaps
cure the whole. In the drain, at F, where the tail of
the sand has a covering of clay, sink tap holes in it;
the lower sand DB, which is damp, must be bled by a
deep drain at B, so that this case is reduced to a modi-
fication of the former ones. It is sometimes unnece-
sary to continue the drain through the sand, since that
absorbs the water readily; and it may be collected by
an arm, on either side at the lower edge, into the next
piece of drain which crosses the clay.

Fig. 14. shows the case where the strata are vertical,
or nearly so, and have their edges in the face of the
declinity. The water will here subside through each of
the open strata, and issue at its lower corner as a single
spring; of course there will be a line of these springs
along the foot of every declivity, which are altogether
unconnected with each other; and as the foot of the
declinity will be covered to some height with the rubbish
of the strata above, quicksands and quagmires may
be formed thereby. The remedy is to bring up a cut
for a tail drain BA, to run a drain along under the level
of the springs, and then to make small cuts into every
spring at a proper level in the subsoil; or if the
ground be spotty below them, to sink a tap hole below
each spring in the direction of the stratum.

These different cases comprehend only the simpler
situations which are likely to occur in the practice of
drainage; but, if well understood, they will be sufficient
to direct the operations required for the most complica-
ted. Sometimes, happens, that all the different kinds
of draining are required in one field; at other times,
this great complication is only apparent, as in Figs. 10.
and 12, and one drain, judiciously directed, will do more
than a number run merely at random, without previous
investigation. The first thing required is a

careful examination of the strata; and indeed no per-
son can pretend to skill in draining without some degree
of geological knowledge. The inclination of the strata
must also be examined, to judge how they are connect-
ed with the given site, and how a drain or bore may
be directed to reach the spring. It is proper, therefore,
to examine all places where the strata have been laid
bare, as in cliffs, river beds, wells, ditches, quarries, &c.
in the neighbourhood. Where nothing of that kind oc-
curs, the boring irons must be applied for the purpose,
or pits sunk in the soil. If the water rises in these, the
evil and its cure may be discovered at once, and a drain
opened; but it would be very injudicious to do so with-
out previous investigation. The figure of the
ground must also be considered, as that will lead to a
knowledge of the place where the watery bed bursts
out, or is most accessible, and where drains may be most
advisably placed. The probable supply of water may
also be known in this way.

The spirit level is used for laying out the direction of
the drains, and calculating the expense of cutting them.
The height of water in the interior strata may also be
known thereby, by levelling from the surrounding
springs and wells. A very useful common implement
of that nature is shown at Fig. 15, being a kind of quad-
rant made with stout laths, which may be formed and
graduated any where. (A. N.)

DRAKE, SIR FRANCIS, one of the most distinguished
naval commanders and navigators in the reign of Queen
Elizabeth, was born of obscure parents near Tavistock,
in Devonshire, in the year 1545. He was the eldest of
twelve sons of an honest seaman, and was brought up
in the sea-service from an early period of life, under
the care of his kinsman, Admiral Sir John Hawkins.
At the age of 22, he was appointed captain of the Ju-
dith, in the Gulf of Mexico, where he distinguished
himself greatly in the operations against the Spaniards.
In the year 1570, he made an expedition with two
ships against the same people; and having improved
his fortune, as well as enlarged his experience, he sailed
a second time in 1572, with two ships, one of 75, and

another of 25 tons burden, manned with no more than 73 men and boys. With this inconsiderable force he took first the city of Nombre de Dios, and next that of Vera Cruz, by storm, in neither of which did he find much booty, and in the attack of the former received a very severe wound; but as he was retiring to his vessels, he met unexpectedly with 50 mules laden with silver, of which his people carried off as much as they were able to convey. In these expeditions he was effectually assisted by the Simerons, an Indian nation who were engaged in perpetual hostilities with the Spaniards; and, having received from their chief four large wedges of gold, in return for a cutlass, with which he had presented him, he generously threw them into the common stock. Having embarked his men, and the wealth which he had thus obtained to a considerable amount, he arrived safely in England on the 9th of August 1573.

After his return, he fitted out three frigates at his own expense, with which he served as a volunteer on the coast of Ireland, under Walter Earl of Essex, the father of Queen Elizabeth's favourite; and thus procured, through the influence of Sir Christopher Hatton, the countenance of the court. He had long cherished an ardent wish, though he prudently concealed his plan, to conduct an expedition through the Straits of Magellan into the South Sea; and, having obtained the Queen's permission, he set sail on the 15th of November 1577 with a small fleet of five vessels, of which the largest was only 100 and the smallest 15 tons burden, and the whole of which carried only 164 men. In his course he touched at Mogadore on the coast of Barbary, and opened a friendly intercourse with the Moors; passed Cape Blanco, sweeping the sea of all the Spanish vessels that came in his way, and anchored off the Cape de Verdi Islands in the month of January; but the Portuguese having both refused him here a supply of provisions, and fired upon his ships from St. Jago, he seized upon one of their vessels laden with wine, from which he took the pilot Nuno de Sylva, whose knowledge of the American coast proved of the most essential service to him in his future voyage. On the 5th of April, he made the coast of Brazil, where he took two of his ships, after having taken out the provisions which they carried. On the 20th of May, he entered the port of St. Julian's, where he produced his commission, investing him with the power of life and death; and proceeded to try by a court martial his second in command, Mr John Doughty, upon a charge of mutiny and designs against his life. Doughty having been convicted, partly upon his own confession, and condemned to suffer a capital punishment, was required by Drake to make his choice of one of the following terms,—to be ordered to instant execution, to be left on the adjoining continent, or to be carried to England to stand the course of law. The prisoner having chosen the first, and having received the sacrament along with his commander, whom he also embraced previous to his execution, was beheaded on the spot. This has been censured as the most unworthy act of this celebrated commander, and even as having proceeded in part from private revenge; but though it no doubt demonstrates his deficiency in the quality of mercy, it may, in some measure, be vindicated by the consideration, that, on such distant expeditions, the strictest discipline is essentially necessary, both for the success of the object, and the preservation of all concerned. On the 20th of August he passed the Straits of Magellan; and having now only his own ship the Pelican, (to which in the South seas he gave the name of the Hind,) he continued his voyage along the coast of Chili and Peru, capturing the ships of the Spaniards, and frequently attacking their settlements on the shore. He then proceeded along the western coast of North America as far as the 48th degree, in hopes of finding a passage to the Atlantic; but being disappointed in his plan, he landed upon the adjacent continent, which he named New Albion, and of which he took possession in the name of Queen Elizabeth. Knowing that a return by the Straits of Magellan would expose him, by the lateness of the season, to dangerous storms, as well as to be attacked at a great disadvantage by the Spaniards, he boldly stretched across the Pacific Ocean, and, in less than six weeks, reached the Molucca Islands. Touching at Celebes and Java, he doubled the Cape of Good Hope on the 15th of June, and entered the harbour of Plymouth about the end of September 1580, having completed the circumnavigation of the globe in two years and ten months. The success of his enterprise, and the riches which he had acquired, excited much discussion in England, and very opposite opinions were expressed on the merit of his exploits. Some were disposed to regard him as little better than a pirate, and conceived that the approbation of his proceedings by the government would be attended with fatal consequences to the interests of commerce; while others declared his successful undertaking to be highly honourable to the maritime skill of his country, and his reprisals upon the Spaniards to be fully justified by their own faithless practices. But in the month of April 1581, his majesty gave a public testimony of her approbation of his conduct, by going on board his ship at Deptford, and conferring upon him the honour of knighthood. She also gave directions that his vessel should be preserved as a monument of his own and his country's naval reputation; and whilst the length it began to decay, a chair made of its planks was presented as a curiosity to the university of Oxford. In 1585, he was sent with a fleet of 20 sail to attack the Spanish settlements in the West Indies; and, in this expedition, he took the cities of St. Jago, St Domingo, Carthagena, and St Augustine. In 1587, he was dispatched to Lisbon with a large fleet, with which he proceeded to Cadiz, and destroyed in the harbour more than 10,000 tons of shipping, which were intended for the invasion of England, and afterwards way-laid and captured a rich Spanish Indiaman, the charts and papers of which suggested the first idea of an India company in this country. In 1588, having been appointed vice-admiral under Lord Howard of Effingham, he acted a distinguished part in the attack and destruction of the Spanish armada, and particularly made prize of a large galleon, which yielded without the least resistance to the mere terror of his name. The year following he was entrusted with the command of the fleet which was sent to restore Don Antonio to the throne of Portugal; but owing to a disagreement between him and Sir John Norris, who commanded the land forces, the enterprise completely failed of success. He was still more unsuccessful in 1594, when, in conjunction with Sir John Hawkins, he proceeded upon a second expedition against the Spanish settlements in the West Indies; and by the vexation which this disappointment produced, he was thrown into a lingering fever, of which he died near Nombre de Dios in the month of January 1596, in the 31st year of his age. In his person, Sir Francis Drake was of low stature, but well made, had a broad open chest, a very round head, large clear eyes, a fair complexion, and a fresh, cheerful, engaging countenance. He was thoroughly acquainted with navigation.
in all its branches, and especially with the application of astronomy to the objects of his profession. Though in other respects destitute of education, he possessed a wonderful portion of natural eloquence, and is said to have scarcely ever been heard to utter a feeble or ungraceful expression. He was, on proper occasions, uncommonly generous, but, at the same time, a great economist in the management of his property. Though rather rough and boastful in his manners, he was highly estimable in his private character, anxiously careful of those who were under his command, and displayed the greatest civility and humanity to those whom the fortune of war placed in his power. In all his enter-

D R A M A.

Drama, from the Greek word ὑπάρχειν, is a poem accommodated to action; a poem in which the action is not related, but represented.

The drama is the most directly imitative species of poetry, perhaps the only one that can strictly be said to be imitative.

The drama naturally divides itself into different provinces, according to its means, or according to its ends.

When the means exceed those of mere recitation and simple action, and include dancing and singing, or instrumental music, as important or necessary parts of the performance, we call it Opera, or Melo-drama, and when the subject is sacred, Oratorio. When it excludes recitation, we call it Pantomime. If we divide the drama by its objects, when the end is simply to excite laughter, it is Farce. When rising above the mere object of visibility, it gives a natural, amusing, and interesting draft of manners and character, it is called Comedy. When the end accomplished is to excite sympathy in the strongest degree, and particularly the emotions of compassion and terror, the composition is entitled to the name of Tragedy. To the latter division of the drama, viz., that which arises from the distinction of its objects, we shall principally attend.

As the spectacle of human existence, which the drama professes to imitate, exhibits in the original a constant alternation and mixture of gay and sorrowful objects, it occurs as an obvious question, whether the separation of tragedy and comedy be an artificial or natural distinction? and as a corollary question, whether, on just principles of taste, they ought to be kept separate? we are disposed to say, in answer to the former query, that the distinction is artificial, and, to a certain degree, conventional. Human life, it must be owned, is for ever promiscuous in her exhibitions of the great and the trivial, and of the cheerful and miserable; so that a constant succession of either solemn or mirthful scenes, is a departure from probability. We believe also, that the early history of all national dramas, not even excepting the Greek, would discover them to have been tragi-comic; and the strongest advocates for a legal and secret separation of the gay and the grave dramas cannot deny, that early genius has succeeded in giving pictures of life of this motley contexture, in many instances delightful and faithful to nature. Yet the progress of human taste has also visibly led to demand an unity of effect in all the productions of the fine arts, and as taste is only the power of judging from a comparison of models, it is not a sufficient defence of tragi-comedy, that it pleases a barbarous age. When it is admitted, therefore, that the above distinction of the provinces of the drama is artificial, we must regard the term artificial as denoting the result of human judgment with respect to art. We must not take the word nature, also, in too strict a sense, as the object of the imitation of art. Nature herself, as Sir Joshua Reynolds has observed, must not be too closely imitated. The imitation of existence is only valuable, in as far as it excites a decided and consistent train of emotions. Abrupt or equivocal feelings are much less satisfactory, than the full sway of those, which, by the magic of genius, are made pleasingly continuous and predominant over the whole soul, whether the feelings to be indulged are those of pathos or humour. The only limitation of this general remark respecting the pleasure of human emotions, is, that a certain degree of change may heighten the pleasure by relief. But still that relief must not amount to absolute and extreme contrast. It may be deduced from this reasoning, if admitted, that though the tone of tragedy and comedy may occasionally approach each other, their highest characteristics should never be equivocally blended.

Tragedy has been justly defined by the ingenious Hurd, Tragedy, to be that species of dramatic composition, of which the end is, to excite the passions of pity and terror, and perhaps of some others nearly allied to them. From this definition of the objects of tragedy, he concludes that actions, not characters and manners, are the chief objects of representation. By curiosity in actions and events, our hearts are moved; by curiosity in manners and characters, our minds are amused. In our deep emotion at a tragedy, it is the fortunate or unfortunate issues of events, that, in the first instance, agitate our hearts;—plot and solid action are of the first consequence to tragedy. Still the manners and characters are so far essential to it, that our grief or joy in the catastrophe, depends on our love or hatred of the leading characters; and the probabilities and truth of manners are indispensable to create illusion, and to secure our belief. The genius of comedy, while it implies that Comedy, display of humour which provokes risibility, supposes also genuine representations of nature, (not caricatures, like farce,) and derives its beauty, perhaps, in the first degree, from fidelity to the truth of life. As a painting of familiar nature, comedy classes and specifically distinguishes the difference of human character, and in the perfection of the art, requires, no less exclusively, and more minutely than tragedy, an observation of all the shades and varieties in the moral physiognomy of man.
Thus in comedy, though a plot be necessary, yet a good plot is not so essential to it as to tragedy. On the contrary, too good a plot, if I may say so, that is, a plot which draws away our curiosity from character to incident, is destructive of the highest excellence of comedy. This is remarkably felt in those busy plots, where the authors have themselves the trouble of painting human nature by surprising events and sudden revolutions. Passions in a tragedy, on the contrary, is the result of the entire action, i.e., of all the circumstances of the story taken together, comprising the complex of events. Comic humour in barbarous times is all practical; in refined times, it becomes spiritual. The simpleton of Molière is exquisitely ludicrous, when he embraces the greatest rogue on the face of the earth, and supposes him the only honest man in Paris. In a Spanish plot, the humour would not be in supposing a rogue an honest man, but in mistaking one person for another. A failure, as Hurd observes, in the just arrangement and disposition of the parts, may then affect what is the essence of tragedy. On the contrary, humour, though brought out by action, is not the effect of the whole, but may be distinctly evidenced in a single scene; as may be eminently illustrated in the two comedies of Fletcher called The Little French Lawyer, and The Spanish Curate. The nice contexture of the fable, therefore, though it may give a pleasure of another kind, is not so immediately required to the production of that pleasure, which the nature of comedy demands. Much less is there occasion for that labour and ingenuity of contrivance, which is seen in the intricacy of the Spanish fable. Yet this is the taste of our comedy; our writers are all for plot and intrigue, and never appear so well satisfied with themselves as when (to speak in their own phrase) they have a great deal of business on their hands. Indeed they have reason, for it hides their inability to colour manners, which is the proper, but much harder province of true comedy. When Hurst said this, Sheridan had not revived the genius of British comedy; but there is something in the remark which still applies to the plot-makers of the present stage. Tragedy, he adds, succeeds best when the subject is real; comedy, when it is feigned. What would this say, but that tragedy, turning our attention principally on the action represented, finds means to interest us more strongly, on the persuasion of its being taken from actual life; while comedy, on the other hand, can neglect the scrupulous measures of probability, as intent only on exhibiting characters, for which purpose an invented story will serve much better. The reason is, real action does not ordinarily afford variety of incidents enough to shew the character fully; feigned action may.

And this difference, we may observe, explains the reason why tragedies are often formed on the most trite and vulgar subjects, whereas a new subject is generally demanded in comedy; the reality of the story being of so much consequence to interest the affections, the more known it is, the fitter for the poet's purpose. But a feigned story having been found more convenient for the display of characters, it grew into a rule, that the story should be always new. — One sees then the reason why tragedy prefers real subjects, and even old ones; and, on the contrary, why comedy delights in feigned subjects, and even new. — The same genius in the two dramas is observable in their choice of characters. Comedy makes all characters general; tragedy particular. — My meaning (continues Hurd,) is, that they are more particular than those of tragedy; for in

the former, no more character is shown than what the course of the action necessarily calls forth; whereas in the latter, viz. comedy, all, or most of the features by which it is usually distinguished, are sought out and industriously displayed.

In the rudest stages of society, we hardly ever find poetry separated from the passions and affections of man; but dramatic poetry, being more complicated in its nature than either the lyric or epic kinds, might be expected to be the last which should become other: and in fact, when the drama first arose in the region of antiquity, which may be called its birth-place, it was not till four hundred years after Homer had brought epic poetry to perfection. The earliest drama that is known is the Greek. Tragedy, or the song of the goat, from παίζεσθαι, a goat, and σαίνο, a song, was among that people at first only a sacred hymn. Bacchus being worshipped as the inventor and cultivator of the vine, the goat was sacrificed to him as its destroyer; — the sacrifice grew into a festival, and the festival into an annual solemnity, which, in process of time, assumed all the pomp and splendour of religious ceremonial. Poets were employed by the magistrates to compose hymns or songs for the occasion; and such was the rudeness and simplicity of the age, that their hands contended for a prize, which, as Horace intimates, was scarce worth contending for, — vicem ob hicem — being no more than a goat, or goat-skin of wine, which was given to the successful competitor.

This was probably the period when Thespis first pointed out the tragic path, by his introduction of a new person, who relieved the chorus, or troop of singers, by reciting part of some well-known history or fable, which gave time for the chorus to rest. All that the actor repeated between the songs of the chorus was called an episode, or additional part, consisting often of different adventures, which had no connexion with each other. When tragedy assumed a regular form, these recitations, which, during its imperfect state, were only adventitious ornaments, became the principal and constituent parts of the drama; the subject of them drawn from one and the same action, retaining the name of episode. Thus the chorus, or song, which was at first the only, and for a long time the principal performance, became gradually and insensibly an inconsiderable, though, according to the structure of the Greek drama, an indispensable part.

From this time, we may imagine the actor or reciter was more attended to than the chorus, as his part had the charm of novelty to recommend it. The songs of the chorus also began to wave from their original subject in praise of Bacchus, and spoke so little of the god of the vintage, that the priests exclaimed against the neglect of him, and their complaint grew into a proverb. From the time of Thespis to that of Aeschylus, however, the history of the Greek drama (if the name can be applied to their strolling performances) is all darkness and conjecture. Tragedy might be said to be created by Aeschylus, who, living in Athens at the brilliant period of the battles of Marathon and Plataea. Fifty years before his time, Thespis had exhibited his rude performances in a cart, and besmeared the faces of his actors with the lees of wine, either for drollery or disgrace. Aeschylus, who was himself author, actor, and manager, took upon him the whole conduct of the drama, improved the scenery and decorations, and brought his actors into a regular and well-constructed theatre; raised his heroes on the euthymus or huskin, invented masks, and introduced splendid habits, with sweeping
trains, that gave an air of dignity to his performers. In order to form any just idea of this primitive form of tragedy which Aeschylus introduced, we must, in the first place, dismiss the idea inculcated by the general mode of printing the Greek plays, that they were divided, like our own, into five acts. The allusion of Horace, it is true, to that number of acts, shows that the Romans had such a division; but the ancient Greek drama was undivided. The oldest editions of the Greek tragedies do not so much as mark a separation of the scenes; and the word act does not occur in that treatise of Aristotle, which gives us a definition of every part of the national drama. The only acknowledged division applied to tragedy, by the critics already mentioned, was its beginning, middle, and end—the prologue, episode, and exode—a division rather formed by the mind of the reader or spectator, than presented mechanically to his eye. The prologue was not like that address to the audience, which passes with us by that name; it was the opening or exposition of the piece, containing all the circumstances necessary to be known, which might not according to Aristotle give an insight into the plot. By the episode was meant all the part of the piece containing the substance of the plot; and the exode contained all the unravelling or catastrophe. But the most remarkable feature of difference between the ancient drama and our own, was the chorus, a group of personages not uninterested in the issue of the events that were going on, but acting chiefly as advisers and confidants of the principal characters. As the principal characters were supposed to be too busy and impassioned in the course of events, the chorus uttered whatever moral reflections the scene suggested; they augmented the pomp of the play by their parades, and they heightened the delight by their music, and (though it ill accords with our idea of the serious drama) by their dancing. In fact, the ancient Greek tragedy must have borne a strong resemblance to the modern Italian opera. The number of persons composing the chorus was probably at first indeterminate. Aeschylus, we are told, brought no less than fifty into his Eumenides, but was obliged, by the civil authority, to reduce them to twelve. Sophocles was afterwards permitted to add three, a limitation which, we have reason to imagine, became a rule to succeeding poets. To modern popular taste, as indeed experience has proved it, nothing is less conducive to dramatic illusion, than a group of such half neutral and moralizing personages as the ancient chorus exhibited. Yet the chorus has found its advocates even among a high order of men of taste and genius. Milton, in his zeal for classic lore, wrote his Samson Agonistes, on the severest model of antiquity; and Mason endeavoured, though without much success, to familiarize a British audience with the lyrical strophes and antistrophes of choral poetry. In justification of this attempt, he contends, in a letter prefixed to his Elfrida, that whatever play-makers may have gained by rejecting the chorus, the true poet has lost considerably by it. For he has lost a graceful and natural resource to the embellishment of picturesque description, sublime allegory, and whatever else comes under the denomination of pure poetry. "Shakespeare," he says, "had the power of introducing this naturally, and, what is most strange, of joining it with pure passion; but I make no doubt, if we had a tragedy of his formed on the Greek model, we should find it more frequent, if not nobler instances of his high poetical capacity. I think you have a proof of this in those parts of his historical plays, which are called choruses, and written in the common dialogue metre. And your imagination will easily conceive, how fine an ode the description of the night preceding the battle of Agincourt would have made in his hands, and what additional grace it would receive from that form of composition." He proceeds, in another letter, to notice that superior variety and majesty, which the chorus necessarily added to the scene of the drama, by uniting the harmony of the lyre to the pomp of the bascin. The point on which he chiefly insists is, that of its being a vehicle for moral and sentiment, so material that he conceives nothing can atone for the want of it. In these parts of the drama (he says) where the judgment of a mixed audience is most likely to be misled by what passes before the view, the chief actors are generally too much agitated by the fervours passions, or too much attached by the tender ones, to think coolly, and impress on the spectator a moral sentiment properly. A confidant, or servant, has seldom sense enough to do it; never dignity enough to make it regarded. Instead, therefore, of these, the ancient poets resorted to the chorus; they were not only capable of seeing and hearing, but of arguing, advising, and reflecting."—"If you ask me, (he continues,) how it augmented the pathetic? I cannot give you a better answer than the Abbé Vatry has done in his dissertation on the subject, published in the Mémoires de l'Acad. des Insd. &c. It effected this," says he, "both in its odes and dialogue. The wonderful power of music and the dance is universally allowed; and as these were always accompaniments to the ode, there is no doubt but they contributed greatly to move the passions. It was necessary, that there should be odes or intermedes, but it was also necessary, that these intermedes should not suffer the minds of the audience to cool; but, on the contrary, should support and fortify those passions which the previous scenes had already excited. Nothing imaginable could produce this effect better than the choral songs and dances, which filled the mind with ideas corresponding to the subject, and never failed to add new force to the sentiments of the principal personages. In the dialogue, also, the chorus served to move the passions, by shewing to the spectators other personages strongly affected by the action. A spectacle of such a kind, as is fitted to excite in us the passions of terror and pity, will not of itself so strongly affect us, as when we see others also affected by it. The painters have generally understood this secret, and have had recourse to an expedient similar to that of the chorus of the poets. Not content with the simple representation of an historical event, they have also added groups of assistant figures, and expressed in their fancies the different passions which they would have their picture excite. Nay, they sometimes enlist into their service even irrational animals. In the slaughter of the Innocents, Le Brun was not satisfied with expressing all the horror of which the subject is naturally capable—he has also painted two horses, with their hair standing on end, and starting back, as afraid to trample on the bleeding infants. This is an artifice which has been often employed, and which has always succeeded. A good poet should do the same; and Iphigenia should not be suffered to appear in the theatre, without being accompanied with persons capable of feeling her misfortunes." Specious as these arguments are, the reflecting reader may have probably anticipated many answers to them.

If the chorus excluded those nuisances of the modern stage, insipid confidants, who are introduced only
for a pretext to let the hero or heroine tell their own
story, the ancient stage substituted what was worse,
whole trains of secret-bearers and confidential advisers.
The chorus prevented soliloquies, which, with us, are
often insipid; but who would exchange such a solilo-
quy as that of Hamlet or Wolsey, for any speech that
could be made to a chorus? The circumstance of the
chorus being unable to follow individuals into privacy,
was in fact a detriment to the Greek stage; for it obli-
ged them to receive secrets in public places, where it
is revolting to think of such communications being
made; as, when Oedipus tells of his incest in the
public street. *Ille bonis joveant,* says Horace, speaking
of the chorus, they are to take the side of the good
and virtuous; but this was not universally the moral merit
of the Greek chorus. The chorus in Antigone, (a tra-
gedy of the moral Euripides), takes the side of the
wicked. It consists of a number of old Thebans, as-
sembled by the order of Creon, to assist at a mock
council, in which he meant to issue his cruel interdict
of the burial of sepulture to the body of Polyxena. This
veteran troop of vassals enter at once into the horrid
views of the tyrant. Besides, the chorus, though in
general moral and friendly advisers, were, from their
confidential character, frequently obliged to be the de-
positaries of horrid intentions, which it would have
been inconsistent with the progress of the plot, as well
as with their characters, if they should have revealed.
With regard to the external pomp and beauty of the
chorus, it is certainly in the power of modern tragedy
to atone for the deficiency of these, by a stronger de-
velopment of the heart; and if the poet cannot inter-
weave in his dialogue the charms of fancy, feeling, and
moral reflection, we shall hardly expect them in a cho-
ral shape. What we have lost by disusing dances in
tragery, it is difficult to conceive; and though the union
of music with poetry may occasionally heighten its ef-
effect, still we know that the Italian operas, which is in
fact the linear descendant, and nearest resemblance of
the ancient Greek drama, has been rather unfavoura-
ble than propitious to the dramatic poetry of Italy.—

To return to *Eschylus:* Only seven of the pieces, out of
ten times the number which he is said to have writ-
ten, have come down to posterity. All these tragedies
betray the infancy of the dramatic art; their beauties
are rather epic than tragic; they display a genius of
bold and gigantic, but of rude character, nourished on
the poetry of Homer, and doing little more than dra-
maticizing his scenes. Indeed, *Eschylus* used to say, that
his pieces were but dishes from the feast of the *liad.* His
seven pieces that have reached us, are, the Pro-
metheus bound—The Persians—The Seven Chiefs be-
fore Thebes—The Suppliant—his Agamemnon—The
Furies—and The Charphoeus. The subject of Prom-
metheus is too mythological to be interesting;—Vulcan,
accompanied by Strength and Violence, the minister of
Jupiter, chains Prometheus to a rock for having stolen
fire, and taught the arts to mankind. The Ocean, and
the ocean Nymphs, and Io, come to listen to the com-
plaints of Prometheus, whom Mercury summons to
tell the secret of which he boasts, namely, the means
which Jupiter may employ to save himself from being
one day hurled from the throne of heaven. Prometheus
haughtily persists in refusing to tell the secret—the
thunder descends, and the sufferer is left to his rock
and tormenting vulture. In all this, it is difficult to
discover any thing moral or affecting. The subject of
his Persians, is the defeat of that people at Salamis;
it is full of recitations, descriptions, prayers, dreams,

and laments, without any regular or interesting
plot. Some aged men, who compose the chorus, await
with anxiety for news of Xerxes' expedition—Atossa,
the mother of Xerxes, relates to them a dream which
has terrified her—A soldier arrives from the army, who
describes the disasters of the Persians—Atossa conjures
up the shade of Darius; and, contrary to the ordinary
intelligence which we expect from such visitors, the
spectre comes, not to reveal a secret to the living, but
to hear from Atossa what has been lately told her by
the messenger, of the defeat of Xerxes. Towards the
close of the play, Xerxes arrives, and is saved with
abundance of trouble: he weeps and groans, and does
little more than recommend to his mother and the old
men, to weep and to groan in concert with him. The
whole tragedy is one tissue of the praises of Athens—
the terrors, the humiliation, and the tears of the Per-
sians. It is easy to conceive a self-sufficient republican
people, intoxicated with recent glory, receiving such a
piece with applause. After the defeat of the Athenians
in Sicily, such extravagant praises would not, perhaps,
have been a substitute for dramatic entertainment.
*Eschylus* tragedy on the death of Agamemnon, has
beauties of a higher cast. There is, it is true, too much
exposition of the catastrophe before it happens, and
the atrocity of Clytemnestra is frigid and unexplained
by sufficient motives. She is neither apparently very
jealous, nor impelled to revenge by any passion that
speaks aloud; she is merely desirous of killing her
husband. Now, in the drama, actions are interesting
only in proportion to the strength of their motives.
We may shudder at motives, but we should never be
left doubtful of their existence or of their impulse,
however criminal it may appear. The tragedy, how-
ever, has traits of sublime and impressive terror in the
part of Cassandra, the Trojan prophetess, who is brought
home a captive, and foresees, though she cannot com-
municate her prediction, so as to be intelligible to those
whom she warns of the impending murder. The pas-
sage is peculiarly fine, when the chorus thus address
her:

Thy own woes thou wallest,
In mournful melody, like the sweet bird
That darkling pours her never-ceasing plaint,
- - - - - - - - and wastes,
In sweetest woe, her melancholy life.

She replies,

"Ah me! the fortune of the nightingale
Is to be envied; on her light poised plumes
She wings at will her easy way, nor knows
The anguish of a tear; whilst on my head
The impending sword threatens a fatal wound."

There is great energy in one of the subsequent bursts
of her agony:

"I burn, I burn, Apollo! O, Apollo!
This likeness, that in a sensual sky
Roll'd with the wolf, (the generous Lion absent,)"
Will kill me! And the sorceress, as she brews
Her filtered cup, will drug it with my blood.
She glorifies, as against her husband's life
She whets the axe—her vengeance falls on him;
For that he came accompanied by me.
Why do I longer wear these useless honours,
This laurel wand, and these prophetic wreaths?
Away! Before I die I cast you from me.
- - - - - - - -

Thou Sun, whose rising beams shall bless no more
These closing eyes! You, whose vindictive rage
Drama.

Hangs o'er my hated murderers, avenge me!

This is the state of man; a passing shadow
Throws down the baseless fabric of his joy;
And when the tablet of his fleeting state
Is character'd with all fidelity,
Comes malice with a sponge, moistened in gall;
And wipes the benogenous images away. *

In three successive tragedies, Æschylus has followed out the history of Agamemnon's family. In Agamemnon, the prince is killed. In the Oreste the death of his son Orestes; and in the Eumenides, Orestes is pursued by the Furies. The two last pieces have something of a nearer approach to that progressive and involved action, which is necessary to an interesting drama. Of the two, the Oreste is perhaps the first piece deserving the name of a tragedy, with which the history of literature presents us; for the Prometheus, the seven chief, the Persians, the Suppliants, and even his Agamemnon, can hardly be pronounced more than terrific theatrical pageants.

From the time that the serious drama commenced in Greece with Æschylus, there appeared in the space of about half a century after him, Sophocles, Euripides, Cherrillus, Aristarchus, Empedocles, Ion, Nonachus, and Cephalus, who disputed for the prizes of tragic genius at the Olympic games before assembled Greece. The fertility of their genius appears immense, when we consider that Æschylus wrote eighty pieces; Sophocles, an hundred and twenty; Euripides, ninety; Cherrillus, an hundred and fifty; and their rivals nearly as many. The entire works of none of those authors have come down to posterity; but from those which have reached us, of the three great masters, the general opinion has assigned the palm of sublimity to Æschylus, of pathos and sentiment to Sophocles, and of tragic art to Euripides. In the plays of Sophocles, however, wetrace a wonderful progress of the art from its crude, though sublime, immaturity in the works of Æschylus. He seems to have had in his mind's eye, a fine idea of the general characters by which human nature is distinguished. He drew mankind such as they should be. We find in him, elevation, dignity, ideal beauty of human character, particularly in his high-minded portraiture of Neoptolemus. His plays have a noble, not a desolate, simplicity; like those of Æschylus, they have plot sufficient to awaken attention, and keep it alive by tender, as well as terrible, emotions. This remark will be found particularly applicable to the sympathy which he excites for the sorrows of Teemessa, the wife of Ajax, in the tragedy bearing that name, and in the two-fold distress of Philoctetes;* and the generous son of Achilles; the one clinging to his benefactor to save him from the desert island, and the other distracted between his duty to Greece and his compassion for the unfortunate man. Sophocles drew men according to the general outline of the ideal beautiful. Euripides, it is alleged, came closer to individual nature, and drew men as they really are. Notwithstanding a passage in Aristotle, which seems to admit, that this was the general opinion of their contemporaries, we confess that, with all deference to higher authority, we are not convinced of the justice of this distinction. The characters of Sophocles, we venture to think, are as entirely true to nature as those of the later dramatist, at least their expressions seem to come more immediately and truly from the heart. Every one must, however, acknowledge Euripides to be, as Aristotle pronounces him, the most tragic of poets. By studying and refining on preceding models, he contrived more consummately tragic situations. He found in, Sophocles sufficient proofs that the natural affections are the first resources of the pathetic. He completed his pictures of these with higher art; he combined the tenderness of Sophocles with the terrors of Æschylus; and new-modelled some of the stories of the former with a splendid and fancy peculiar to his genius. His tragic creations are richer and more full of picture and incident than those of Sophocles. It may be doubted if he any where keeps the heart in more terrible suspense than Sophocles does in his Oedipus; but he launches bolder passions on the stage, as in the jealousy of Medea, and in the love-born frenzy of Phaedra.

We have noticed already the resemblance of ancient tragedy, to modern opera. This circumstance is too important to be slightly passed over. Aristotle tells us in his Poetics, that music (Melopoeia) is an essential part of tragedy; but how it became essential, this philosopher does not inform us. M. Dacier has endeavoured to supply this omission, by suggesting that custom, and the natural passion of the Greeks for music, had incorporated it into their drama. Perhaps the festive origin of tragedy, already mentioned, points it out much better than Dacier's commentary. It explains, at least, sufficiently the musical nature of the choruses. Nor, as Dr Burney has observed, will the custom of setting the acts of a play to music, appear strange to such as recollect that they were written in verse, and that all verse was sung, particularly such as was intended for the entertainment of the public, assembled in spacious theatres, or in the open air, where it could only be heard by means of a very slow, sonorous and articulate utterance. It is true, continues the same writer, that tragedy is an imitation of nature; but it is an exalted and embellished nature; take away music and versification, and it loses its most captivating ingredients. Those who think it unnatural to sing during distress, and the agonies even of death, forget that music is a language that can accommodate its accents and tones to every human sensation and passion; and that the colouring of these upon the stage must be higher than in common life, or else why is blank verse, or a lofty figurative language, necessary? * From these and other circumstances, Dr Burney observes, there can remain no doubt but that the ancient dramas were sung. Dramatic representation having been constantly called by the Greeks μίσρη melody, and by the Latins modulatio cantum, and other musical terms which imply singing. Indeed, so immense was the size of the theatres of Greece and Italy, that we may naturally conclude a musical declamation to have been a necessary consequence of speaking loud; for whoever shouts, halloos, or bawls with sufficient force to be heard farther than common speech can penetrate, makes use of fixed-tones, which if softened would become musical; and it is well known that the tones of speech are too transient and undetermined to be ascertained by those of music, or to be

* We have ventured to make a slight change from the translation of this passage by Potter.
† In the tragedy of Philoctetes.
‡ These we give as Dr Burney's ideas on melo-drama, which, however, his own opinion of the Opera, in another passage, rather contradicts.
audible at a great distance, or in a wide space. This want of natural power of voice sufficient to be heard in the open air, (for the ancient theatre had no permanent covering,) gave rise not only to singing upon the stage, but perhaps to chanting in the church.

The necessity of augmenting the performers' voice by every possible means, likewise first suggested the idea of metallic masks, which were likewise used by the actors upon the principle of speaking trumpets, and that of the echeias, or harmonic vases; two expedients so peculiar to the ancient drama, that it seems necessary to give some account of them. The mask was called by the Romans persona, from personare, "to sound through;" and delineations of such masks as were used in each piece were generally prefixed to it, as appears from the Vatican Terence. Hence dramatis persona, "masks of the drama," which words after masks ceased to be used, were understood to mean persons of the drama. Quintilian, lib. ii, gives a list of invariable masks appropriated to different characters, to which the public had for many ages been accustomed; and Julius Pollux is still more ample in his account of theatrical masks, used in tragedy, satire, and comedy.—Niobe weeping, Medea furious, Ajax astonished, and Hercules enraged. In comedy, the slave, the parasite, the clown, the captain, the old woman, the harlot, the austere old man, the debauched young man, the prudent young woman, the matron, and the father of a family, were all constantly characterized by particular masks. This custom is, in some measure, still preserved in the Italian comedy, and in our pantomime entertainments, which originated from it. "The spectators," says De Bos, speaking of the ancient theatre, "lost little on the side of face-playing by the introduction of masks; for not one-third of the audience were near enough the actor to discern the play of muscles, or workings of the passions in the features of the face, at least to have received pleasure from them; for an expression must have been accompanied with a frightful grimace and distortion of visage, to be perceptible at so great a distance from the stage." With respect to the echeia or vases, the historian of music already quoted observes, that they were used in theatres for the augmentation of sound. Vitruvius, b. v. ch. v. tells us, that they were placed in cells or niches between the rows or seats occupied by the spectators, to which the voice of the actor had free passage; that they were made of brass or earthen ware, and proportioned in magnitude to the size of the building; and lastly, that, in the small theatres, they were tuned in the proportions of fourths, fifths, and octaves, with their replicates; and in theatres of great magnitude, there was a vase to correspond with every sound in the disdiapason, or great musical system, in all the genera. From the existence of those vases, Dr. Burney concludes, that the voices of the actors approached them in fixed and musical tones, modulated in unison with the tones of the vases. Plutarch tells us, that the dithyrambic and tragic poets adopted for their pieces that kind of musical execution, of which Archilochus performed the music to his iambic verses in two different ways, rectifying some of them with an accompaniment, and singing others, while instruments servilely performed the same notes as the voice; and this was the method which the tragic poets afterwards adopted. We learn from the same work of Plutarch, that even the declamatory iambics were accompanied by the ethara, and other instruments; but as the employment of the ethara upon these occasions was not constant, it seems, says Dr. Burney, as if only the general tone of declamation was given to the actor by the musician, as the chord is given to the singer in modern recitative; whereas in the chorus, and other poetry that was sung, the instrument constantly accompanied the voice note for note. Dr. Burney's conclusion is, therefore, that the ancient dramatic writers used a different kind of music for the declamation of the actors, and for the songs of the chorus; the one may perhaps be compared to modern recitative, and the other to chanting in the Roman church. That this music was simple, and intended to render speech more articulate, as well as to fortify passion, both reason and the authority of ancient writers enable us to believe. Plutarch says, that "the choral genius was never used in tragedy." Now if the ancient drama was declared in a species of recitative, it will bring it still nearer the recitative of modern musical dramas, in which no chromatic is ever admitted. Plutarch likewise informs us, that a strict rhythm or measure was not observed in tragedy; another circumstance resembling modern recitative, in which no time is kept but that of the accent and cadence of the verse. And this assertion of Plutarch seems to agree with what Aristotel says in his Poetics, chap. 1. that the dithyrambs, nomes, tragedies, and comedies, use a like number, verse, and harmony, with this difference, that in some all three are employed at once, in others they are used separately. By number or
rythm is here meant regular time, and by harmony mu-

song. In dithyrambs and odes, the verse was always accompanied by melody, rythm, and dance; and in tragedy and comedy, the verse was only recited dur-
ing the tragedy, (we should rather say in all the parts not choral,) but in the choruses it was accompanied by sing-
ing and dancing. The custom of dividing the action from the declamation, ascribed very absurdly by some modern writers to the ancient stage, is quite incredible, and without authority. It is mentioned by Livy, as hav-
ing been done by Livius Andronicus, an old Roman poet, in order to save himself the fatigue of singing in his own piece. The passage of Livy, however, according to the suggestion of M. Duros, may be understood with more probability to imply, that the old poet, who at first sang his canticum, and afterwards danced in the inter-
cludes, alternately having sung till he was hoarse, trans-
ferred the singing to another performer, in order to dance with more force and activity; and that the ode was the custom of making singing and dancing two different pro-
cessions. The story, when applied to the separation of speaking and acting, becomes absurd and incredible.

To speak generally of the Greek tragedy, the works of it which have reached us, certainly present most interesting and beautiful relics of human genius. As an order of dra-
matic architecture, if we may so speak, it was simple, stupen-
dous, and severely regular in its proportions; though some of the wandering plots of Euripides may be deemed an exception to this rule. It was, however, rather the show of events, than of characters or passions; and to one accustomed to the full development of the heart in modern tragedy, the reserved and concentrated expres-
sion of ancient heroes on the stage, will sometimes ap-
pear as unnatural as the masks which they wore. In one respect, modern opinion seems to have done them too much justice. The Greek tragedies were simple, but not so free from tragi-comedy, as may be generally imagi-
ned. If that be tragi-comedy which is partly serious and partly comic, we need not scruple to say, that the Alcestes of Euripides is, to all intents and purposes, a tragi-comedy. There can be little doubt that it had, upon an Athenian audience, the proper effect of tragi-
comedy; that is, that in some places it made them cry, in others laugh. And the best thing we have to hope for the credit of Euripides, is, that he intended to pro-
duce this effect; for, though he may be an unskilful poet who purposes to write a tragi-comedy, he is surely still more unskilful, who writes it without knowing it. We par-
cicularly allude to the scene in which the domestic in Alcestes describes the behaviour of Hercules, and to the speech of Hercules himself which follows. The servant describes the hero as the most greedy and ill-mannered guest he had ever attended under his master's hospitable roof, calling about him, eating, drinking, and singing in a room by himself. While the master and all the rest of the family are in the height of funeral lamentation, he was not contented with such refreshments as had been set before him, but drinks, croaks himself with myrtles, and sings ΑΜΟΤΕΥΩ ΤΑΛΚΡΟΝ, and all this alone.

"Cette description (says Fontenelle) est si burlesque qu'on dirait d'un crocheteur qui est de contrariete." A censure somewhat justified by Euripides himself, who makes the servant take Hercules for a thief. The speech of Heracles philosophizing in his cups, is still more cu-
rious. It is indeed full of the ΠΑΣ ΟΡΙΟ, and completely justifies the attendant's description. It is a true drink-
ing song, recommending the servant to uncloud his brow, enjoy the present hour, think nothing of to-mor-
row, and drown his cares in love and wine. In another tragedy of the grave Euripides, of which only some frag-
ments remain, entitled Menalippe the Wise, there must have been tragi-comic matter of a still more cu-
rious kind. Menalippe was delivered of two children, the fruits of a stolen amour with Neptune. To conceal her shame, she hid them in her father's cow-house, where he found them; and being less of a philosopher than his daughter, took them for a monstrous produc-
tion of some of his cows, and ordered them to be burned.

His daughter, in order to save them without exposing herself, enters into a long physical argument to cure her father of his unphilosophical prejudices about monsters, and portentous births; and to convince him that these children might be the natural offspring of his cows.

The truth is, that we may plainly trace in the Greek tragedy, with all its improvements, and all its beauties, pretty strong marks of its popular and tragi-comic origin; for though the festival of Bacchus was a religious cere-
mony, we must not attach to the religion of antiquity, especially to the worship of Bacchus, the ideas of purity and serious devotion, with which Christianity is invested.

Tragodía, or the Song of the Goat, we are told, was or-
ginally the only dramatic appellation; and when after-
wards the ludicrous was separated from the serious, and distinguished by its proper name of comedy, the se-
paration seems to have been imperfectly made, and tragi-
drama, distinctively so called, seems still to have retained a tincture of its original merriment. Nor will this ap-
pear strange, when we consider the popular nature of the Greek spectacles. Even comedy among the Greeks, in its broadest and most farcical state under Aristophanes, par-
took visibly, on some occasions, of the magnificence, though not of the pathos, of the serious drama. Every one who recollects the choruses of Aristophanes in his "Clouds," will acknowledge that the poet often writes most beautiful and serious lyric poetry; not indeed tragi-
comedy, or moving, but splendid, fanciful, and metaphorical, above the tone of comedy.

The comic drama was not at first cultivated in Greece with the same care as tragedy; but the gaiety of Athens gave it also its reign, and although the man-
ners of Greece never seem to have favoured its true polish and refinement, yet this was not for want of comic writers, since from their earliest one, Crater, to the rise of the Roman stage with Plautus, an int-
erval of two ages, there are reckoned fifty comic poets.

Of these, Aristophanes composed fifty comedies, and Menander and Cratinus one hundred each. Of none but of Aristophanes has any entire play come down to posterity. The Greek comedy has been divided into three epochs; the old comedy, the middle, and the new. The old comedy was mere scandal in the shape of dia-
logue, which launched individuals by their proper name upon the stage. Aristophanes flourished in what was called the period of the old comedy. In the old comedy, the individual object of ridicule was named by his pro-
per name; in the middle comedy, the dramatist was obliged to give a fictitious name to his characters; in the new and civilized comedy, general and purely fictitious characters were substituted for the former scandalous species of satire, before the comic art had aspired to that generalization of character and refinement of spirit, which gives it dignity to rank as the counterpart of tragi-

General character of the Greek tragedy.

Greek comedy.

VOL. VIII. PART i.
Drama.  Comedy, (as an eloquent living writer has observed,) requires a much deeper and more extensive knowledge of the human heart than tragedy: it is less difficult to portray what so frequently strikes the imagination as the picture of distress; it may also be admitted, that tragic characters bear a certain resemblance towards each other, which excludes critical observation, and the models of heroic history have clearly pointed out the path which they should pursue. But it was the process of ages to bring the understanding to that requisite degree of taste and superior philosophy which distinguished the dramatic works of Moliere; and even had as great a genius as this author existed among the Athenians, they would not have understood the beauty of his productions. The taste of the Greeks, (that sensible authoress continues to remark,;) was only good when it was annexed to the imagination—objects of enthusiasm—but defective when it arose from morality and sentiment. The exclusion of women from the Greek theatres, was one of the chief causes of its imperfections; the authors having no motive for concealment, there was no restriction of language necessary to be observed; they were consequently deficient in grace, elegance, and modesty. The use of masks, and speaking trumpets, and all the fantastical customs of the ancient theatre, disposed the mind, like caricatures in drawing, to study the grotesque and unnatural. Aristophanes sometimes availed himself of the gross jests and buffoonery of the populace—he likewise presented the reverse of what was vulgar and inelegant, but it was never a clear representation of situations, or an accurate description of characters, that he explained.

The greater part of his dramatic works were relatively connected with the events of the times in which they were written. The art of inquiring popular curiosity by a romantic intrigue was yet unknown; it was always an easy matter to please the people, by turning their chiefs into derision. The comedies of Menander and Theophrastus made a great progress in dramatic decency, and in the knowledge of the human heart; both these writers had the advantage of living a century after the time of Aristophanes, when the licentiousness of an Athenian democracy must have been so unfavourable to the fine spirit of comedy. The high character of Menander, which is given by Plutarch, leaves us room to lament, that only fragments of his works have been preserved.

That idolatry which we pay to Shakespeare seems to have been paid to Menander by antiquity. "Oh! Menander and Nature," says Aristophanes the grammarian, "which of you copied from the workmanship of the other?" and Julius Caesar, in giving Terence the name of half Menander, and at the same time lamenting his deficiency in the vis comica, implies that the Greek dramatist possessed the latter gift in common with the qualities so much admired in the Roman. Besides their regular comedy, the Greeks had dramatic ΣΑΤΥΡΙΚΑ, or farces, which were probably the most ancient species of dramatic writing. These satires were so called from their actors, who personified the Satyrs, the imaginary attendants of Bacchus. The only specimen which we have of this species of entertainment, is the Cyclops of Euripides, which is, in fact, like Tom Thumb, a tragedy burlesqued. They were performed, says Mr Pinkerton, between the acts of the comedies or tragedies. Mr Pinkerton should have known, that the Greek drama had no acts nor intervals.

Masters as the Romans were of the ancient world, they were in literature only the scholars of the Greeks. It appears, indeed, from a passage in Varia, who speaks of an author of Tuscan tragedies, that the dramatic art was known in Italy at a very early period; but we can no more judge of the progress of the art, in such distant times by this passage, than we can gather the history of the kings of Babylon by the fragments of Sancliangon. The Romans, while extending their arms over Italy, left to Etruria her drama and theatre such as it was. On one occasion, we are informed, that, during a pestilence at Rome, the Sybiline oracle predicted, that it could not be stopped without some stage-players being sent for from Etruria. The performers accordingly came; but as the pestilence did not subside, they were dismissed with discredit for having belied the oracles, while the oracles themselves were never blamed for their false prediction. Horace informs us, that in the repose and leisure which followed the Punic wars, the Romans began to study the tragic and comic poets of Greece, and made attempts to transfer their beauties in translation. This, in fact, was the origin of the drama at Rome; but when regard to the epoch, one is tempted to believe, that the text of Horace has been vitiated. The reign of genuine comedy at Rome appears to have been during, not after, the Punic wars, from Naevius to Terence and Afranius, about the space of a century. It was in this interval that Licius, Cecilius, Plautus, Lucilius, and Terpilus flourished. Terence died thirteen years before the destruction of Carthage. It was not then, as Horace has said, post Punica bella, that the Romans began to copy the Greeks. Of the only two whose works remain to us, Plautus and Terence, the one has copied Cratinus, and the other Menander. It has been said, that Plautus imitated Aristophanes, which is assuredly unfounded. An imitation of Aristophanes would not have been tolerated by a Roman audience. The genius of Roman manners, which communicated a decency and dignity to the lowest orders, would have revolted at such atrocious characters. The new comedy alone, that which contained no personal satire, was fit to be received among a people so proud and austere. There is some room, indeed to suspect, that Naevius, the first of the comic Latin poets, tried the experiment of personality; and it was probably on that account that he was chased out of Rome by the aristocratic faction. If so, his example was a caution to succeeding poets; for though it was permitted to comedy to represent all classes of society, from the lowest to those of consular rank, there is no appearance of its having dealt in individual abuse or allusion. The age of Augustus does not seem to have produced a single celebrated comic poet; and in the degeneracy of manners which succeeded to the loss of Roman liberty, the rage for pantomime destroyed all genuine relish for the drama. Plautus and Terence, we are told, borrowed from the Greeks. At the bare mention of imitation and borrowing, the haughty is apt to be much impressed in disfavour of the writer to which it is imputed. If we possessed not the works of Homer, and only heard in general, that Virgil was a copyist of the Grecian epic poet, we should not be able to give credit to the author of the Aeneid, for the spirit of beauty that breathes in his writings, independent of all obligations to the Aeneid. It is always to the disadvantage of an ingenious writer, who may be taxed with plagiarism, not to have his work confronted with his alleged model. This

* Casaubon in his treatise on the satirical poetry of the Greeks and Romans, has established a distinction between the satires of the two nations. Those of the Greeks were little pieces for the stage; those of the Romans were moral invective poems.
consideration should prevent our being swayed implicitly by the indefinite charge of plagiarism, attached to Plautus and Terence. The works of Cratinus and Menander, cannot now be consulted, to ascertain the extent of their debt; but the humour of Plautus, and the elegance of Terence, still remain to us, and if they were imitators, it must be owned that they were good ones. The comic vein of Plautus, it may be said, is coarse, monstrous, and limited in its range of characters. Yet it is from this Plautus, that modern comedy has borrowed some of its richest materials. His Miser, the original of Molière's Avare, has not been so entirely transmuted or recreated in the hands of the French dramatist, as the French critics would lead us to believe. His Twin Brothers is evidently the source of Shakespeare's Comedy of Errors, with the difference, that Shakespeare's plot is more improbable, and much less skilfully conducted.

With regard to Terence, he is said to have joined together several of the plots of Menander into one of his own; a circumstance which entitles us to suspect, as the plots of Terence are remarkably simple, that the originals must have been thin and deficient in action, and that he improved on them with considerable dramatic art. Comedy at Rome, ventured to delineate Roman manners. Tragedy was more timid. It attempted, indeed, sometimes to rise above its models. The subject of Iphigenia in Tauris was enriched by the genius of Pacuvius. It is to him that we owe that affecting scene of a combat of friendship, where Pylades wishes to die for Orestes; but although the tragedy of Rome borrowed something of her stateliness and heroic genius, it appears almost invariably to have attached itself to Greek subjects. It is known, that Andronicus was a mere translator, and the titles of the tragedies known to be written after him, betray the same origin, as the Orestes of Pacuvius, the Elidus of Accius, the Eclipsus of Julius Caesar, the Ajax of Cassius and of Octavius, the Thesmophoria of Gracchius and that of Varius, the Medea of Ovid, and the Theatre of Seneca.

From the Roman poets till the revival of modern learning, there is a blank of many ages in the history of the drama, as in that of all the other branches of literature. About the eighth century, Europe was principally carried on by means of fairs, which lasted several days. Charlemagne established many marts of this sort in France; as did William the Conqueror and his Norman successors in England. The merchants, who frequented these fairs in numerous caravans or companies, employed every art to draw the people together. They were therefore accompanied by jugglers, minstrels, and buffoons, who were no less interested in giving their attendance, and exerting all their skill on these occasions. As now but few large towns existed, no public spectacles or popular amusements were established; and as the sedentary pleasures of domestic life and private society were yet unknown, the fair time was the season for diversion. In proportion as these shows were attended and encouraged, they began to be set off with new decorations and improvements; and the arts of buffoonery being rendered still more attractive by extending their circle of performances, acquired an importance in the eyes of the people. By degrees the clergy observing that the entertainments of dancing, music, and mimicry, exhibited at these projected annual celebrations, made the people less religious, by promoting idleness and a love of festivity, proscribed these sports, and excommunicated the performers. But finding that no regard was paid to their censures, they changed their plan, and determined to take these recreations into their own hands. They turned actors themselves, and, instead of profane mummeries, presented stories taken either from legends or the Bible. This was the origin of that incongruous thing called sacred comedy. The death of St Catherine, acted by the monks of St Denis, rivalled the popularity of the professed players. Music was admitted into the churches, which served as theatres for the representation of holy entertainments. The festivals among the French, called Le fet de fax, de l'ane, du des, at length became greater favourites, as they certainly were more capricious and absurd than the interludes of the buffoons at the fairs. These are the ideas of a judicious French writer, given by Warton in his history of English poetry.

Voltaire's theory, Warton continues, on this subject, is also very ingenious, and quite new. Religious plays, he supposes, came originally from Constantinople, where the old Grecian stage continued to flourish in some degree; and the tragedies of Sophocles and Euripides were represented till the fourth century. About that period, Gregory Nazianzen, an archbishop, a poet, and one of the fathers of the church, banished pagan plays from the stage at Constantinople, and introduced select stories from the Old and New Testament. As the ancient Greek tragedy was a religious spectacle, a transition was made on the same plan, and the choruses were turned into Christian hymns. Gregory wrote many sacred dramas for this purpose, which have not survived those inimitable compositions. One, however, his tragedy called Xενεσίς παρεια, or Christ's Passion, is still extant. In the prologue, it is said to be in imitation of Euripides, and that this is the first time the Virgin Mary had been produced on the stage. The fashion of acting dramatic scenes, in which, at first, a due degree of gravity and solemnity was observed, but at length adopted from Constantinople by the Italians, who framed, in the depth of the dark ages, on this foundation, that barbarous species of theatrical representation called Mysteries, or Sacred Comedies, and which were soon afterwards received in France. This opinion will acquire probability, if we consider the early commercial intercourse between Italy and Constantinople; and although the Italians, at the time when they may be supposed to have imported plays of this nature, did not understand the Greek language, yet they could understand, and consequently could imitate, what they saw. In defence of Voltaire's hypothesis, it may be farther observed, that the Feast of Fools and of the Ass, with other religious farces of that sort, so common in Europe, originated at Constantinople. They were instituted, although perhaps under other names in the Greek church, by Theophylact, patriarch of Constantinople, probably with a better design than is imagined by the ecclesiastical annalists, that of wean...
Drama.

ing the minds of the people from the Pagan ceremonies, particularly the Bacchanalian and calendar ceremonies, by the substitution of Christian spectacles partaking of the same spirit of licentiousness. But a still earlier, and more curious, specimen of theatrical representation of sacred history, is mentioned by the historian of English poetry. Some fragments (he says) of an ancient Jewish play on the Exodus, or the departure of the Israelites from Egypt, are yet preserved in Greek fragments. The principal characters of this drama, are Moses, Sapphira, and God from the bush. Moses delivers the prologue, or introduction, in a speech of sixty lines, and his rod is turned into a serpent on the stage. The author of this piece was Ezekiel, a Jew, who was called Ὅ τὸν ἔκκαλον τραγωδίων παίδας, or the tragic poet of the Jews. Mr. Warton is of opinion, that Ezekiel composed this play in imitation of the Greek drama, at the close of the second century after the destruction of Jerusalem; and even in the time of Barocbas, as a political spectacle, with a view to animate his countrymen with hopes of a future deliverance and restoration. Boileau, in the subjoined verses, considers the ancient pilgrimages to have introduced those sacred mysteries into France.

Origin of the modern drama.

Ches nos devoue ayeux le theatre aborde.
Put long-tems dans la France une plaisir ignoré
De Pelerins, dit on, une troupe grossiere
En public, a Paris, y monta la première ;
Et, dormant sotre en la simplicité,
Jona les saints, la Vierge, et Dieu, par pieté.
Le savoir, a la fin, disant Ignorance,
Et voir, de ce projet, la devote imprudence;
On chasse ces docteurs prêchant sans mission,
On vnit renante Hector, Andromaque, Ilium.

The authority to which Boileau alludes is Mones- trier, an intelligent French antiquary. The pilgrims who returned from Jerusalem, St James of Compos- tella, St Beannus of Provence, and others, composed songs on their adventures, intermixing recitals of passages in the life of Christ, descriptions of his crucifixion, of miracles, and martyrdoms. To these tales, which were recommended by a pathetic chant, and a variety of gesticulations, the credulity of the multitude gave the name of visions. These pious itinerants travelled in companies, and taking their stations in the most public streets, and singing with their staves in their hands, and their lutes and mantles fantastically adorned with shells and emblems painted in various colours, formed a sort of theatrical spectacle. At length their performances excited the charity and compassion of some citizens of Paris, who erected a theatre, in which they might exhibit their religious stories with the addition of scenery and decorations. To these (continues the ingenious author already quoted) who are accustomed to contemplate the great picture of human follies which the unpolished ages of Europe hold up to our view, it will not appear surprising, that the people who were forbidden to read the events of the sacred history in the Bible, in which they were faithfully and beautifully related, should, at the same time, be permitted to see them represented on the stage; disgraced with the grossest improprieties-corrupted with inventions and additions of the most ridiculous kind-stilled with impurities, and expressed in the language and gesticulations of the lowest farce. On the whole, the mysteries appear to have originated among the ecclesiastics, and were, most probably, first acted, at least with any degree of form, by the monks. The play of St Catherine was performed by the monks at Dunstable Abbey, in the eleventh century, under the superintendence of Geoffroy, a Parisian ecclesiastic; and the exhibition of the Passion, by the mendicant friars of Coventry and other places.

From the end of the 11th to the verge of the 14th century, the troubadours were the pre-eminent poets of Europe; but it does not appear that they contributed directly, either to the formation of a regular theatre, or to the refinement of dramatic taste. The tragedies of Anselme Faydit, one of the principal poets of this class, are, however, mentioned as appearing early in the thirteenth century; and one of them, written about the year 1210, entitled Hervis de les Preures; the Hervis of Priests, is still extant. It is a violent satire against the Roman clergy. Faydit, it appears, was both an author and an actor. About the year 1280, the poet Parusols, another troubadour, composed Les cing belles tragedies des Gestes de Johanne Bayne de Naples. This Jane, queen of Naples, was a monster, who, at eighteen years of age, assassinated her husband, and who finished her career by being smothered between two mattresses. The troubadour, who celebrated her exploits and death, was her contemporary, and must have celebrated her crimes while she was yet living.

During the fourteenth century, the dramatic history of Europe presents nothing but sacred mysteries. The church itself might, indeed, be said to become a theatre; festivals were not merely celebrated, but represented. On the death of the three kings, (the festival after Christmas, still called Hogmanay in Scotland,) three priests, habited like kings, conducted by the figure of a star which appeared at the top of the church, went to a manger, and offered their gifts. The mysteries were, in all probability, for the most part acted with dumb show. To trace the first transition from these to the regular drama, or to ascertain which of the nations of Europe had the honour of first making that transition, is a task of extreme difficulty. It seems, however, upon the whole, most admissible, that Italy may first claim that distinction. In the age of Lorenzo de Medici, (says the elegant historian of that house,) those ill-judged representations (the mysteries) began to assume a more respectable form, and to be united with dialogue. One of the earliest examples of the sacred drama, is the Rappresentazione of St Giovanni and St Paolo, by Lorenzo de Medici. Cionacci conjectures, that this piece was written at the time of the marriage of Maddelena, one of the daughters of Lorenzo, to Francesco Cibo, nephew of Innocent VIII, and that it was performed by his own children; there being many passages which seem to be intended as precepts for such as are entrusted with the direction of a state, and which particularly point out the line of conduct which he and his ancestors had pursued, in obtaining and preserving their influence in Florence. The concluders of Lorenzo in this attempt to mollify the imperfect state of the drama, were Fco Belcari, Bernardo Pulei, and his wife Madonina Antonia de Tanini. That Lorenzo had it in contemplation to employ dramatic composition in other subjects, is also apparent. Among his poems, there is found an attempt to substitute the lives of the ancient histories, the saints and martyrs of the Christian church; but the jealous temper of the national religion seems, for a time, to have restrained the progress which might have been otherwise made in this important department of letters. After a faint dawn in the tragedies of Galietto, Antonio da Pistoia, and Bernardo Accolti, the rise of the Italian drama properly commences with Trissi-
This tragedy was represented in Rome 1515, in the presence of Leo X, to whom it was dedicated, and under whose auspices it was written; and, in the year 1562, when a wooden model of the famous Olympic theatre of Palladio was erected, for trial, in the Palazzo del Ragione, the Sophonisba of Trissino was selected for representation. The historians of Vincenza dwell with pride and pleasure on the splendid of this spectacle, and on the great concourse of nobility, from even the most distant parts of Lombardy, who assisted. This tragedy is written in verse sciolto; and the author, following the Greek model, conducts his plot with great simplicity; only interrupting the course of the action with the aedes, and occasional observations of a moralising character. Sophonisba was soon known beyond the Alps; and, according to Voltaire, it was from the Sophonisba of Trissino that the French learnt the dramatic rules. Encouraged by the success of Trissino, his contemporary and friend Giovanni Ruccelai, nephew of Lorenzo de' Medici, and cousin-german of Leo X, entered the dramatic career. In the year 1516, his Rosmunda was recited in his garden at Florence, in the presence of Leo. This tragedy is founded upon a story of strong interest in the history of the Lombards, which is related with simplicity and perspicuity in the Istoria Fiorentina of Machiavelli, and splendidly and minutely detailed in the luminous page of Gibbon. Mr Roscoe has observed, on this tragedy, that Ruccelai has preserved his heroine from the crimes of prostitution and assassination, and has introduced a disinterested lover in the person of Almcnilde, who executes vengeance on the king from generous and patriotic motives. In justice to the author, it must also be observed, that the horrid incident upon which the tragedy is founded, is narrated only, and not represented, before the audience.

The rest of the sixteenth century presents a list of tragic writers, many of whose works are spoken of in the highest terms by Graovina Riccoboni, and other critics of equal authority. Among these, Giambalista Geronembe is entitled to notice, for being the first who divided the Italian drama into acts and scenes, and making the prologue independent of the piece, which had formerly, according to the Aristotelian canon, formed an awkward integral part of it. Cinthio is memorable for having afforded, in his novels, many materials to Shakespeare. Tasso's Torrismonda ought not to be forgotten; nor Manfredo, the friend of Tasso, who anticipated the subject of Semiramis, afterwards adopted by Voltaire. In the course of the same century, the pastoral comedy became popular; which, whatever the enthusiastic votaries of Tasso and Guarini may say, introduced representations of life the most affected and unnatural, and must have contributed to denaturalize the tone of the rising drama. Riccoboni gives the following general character of the Italian tragedy of the sixteenth century: The tragedies composed from the year 1500 to 1600, or thereabouts, have been found to be too savage, and have not produced pleasure. In short, the horrible was pushed to such excess, that it disgusts the Italians. Poets were not contented to make sons kill their mothers, and fathers their children, but urns were brought upon the stage, from which the limbs of the massacred innocents were piece-meal produced before the spectators.

The 17th century may, with little injury to the dramatic reputation of Italy, be passed over in silence. The rage for the musical drama, which was kindled by some favourite productions of Count Fulvio Testi, Dr Burney, with all his enthusiasm for music, confesses to have been ruinous to true tragedy. The degeneracy of the Italian stage is, however, ascribed to a cause still deeper than partiality for music, by an eminent critic of that country, whose opinion is well entitled to notice. We allude to the Count de Calsibigi, who, in his letter to the celebrated Alfieri, ascribes it ultimately to the want of proper theatres. "Why," says that critic, "has no Italian author produced a tragedy which may be compared with the pieces of the Greek, or even of the French stage, since in every other branch we have poets without number? Why, as if despairing of recovery, have they returned back to those musical dramas, which having become ridiculous in the last century, have been since made more tolerable by Apelle Zeno, and afterwards perfected by Metastasio? Since the Sophonisba of Trissino, which was acted at Rome, and since some other tragedies (our first attempts in the art) represented at Florence and Ferrara, we have indeed never wanted poets, who have continued to write new pieces, and who have succeeded in producing them upon the stage. But what kind of stages were these? sometimes theatres belonging to the court, but most commonly to private noblemen, who caused them to be erected in their palaces and villas. Upon these temporary stages, select tragedies were represented a few times by the courtiers of the prince, or by private parties of ladies and gentlemen. Thus, Italy having never had a permanent tragic theatre, nor actors by profession, these private representations could only be called transient attempts, from which the art received little or no advantage. It was worse, (Calsibigi continues,) when those companies of actors, who have always reigned upon the Italian stage, got possession of those more or less imperfect tragedies, when they were made public by the press. Every body knows, (says he,) of what absurd and awkward buffoons these wandering troops are generally composed. Every body knows, that the greater part of these barbarous actors, besides being taken from the lowest and most uneducated part of the people, is born in those provinces where our language is spoken with the least purity, both in the grammar and in the pronunciation. Therefore, these actors lisping a tragedy, produce the same effect upon their hearers, as the tragedies of Racine or Voltaire would produce at Paris, if they were recited in the provincial brogue of Gascony or Picardy. We all know, to what ridiculous, ill-dressed, awkward, and even ugly females, the parts of the Phedra, Andromache, Semiramis, and Zara, are given to be torn in pieces in the jargon of Bologna, Lombardy, or Genoa; and to be recited or acted without elegance or grace, in the style of the beggar women in the streets. Thus the entire want of a permanent and well conducted theatre, and the more important deficiency of proper actors, hindered our poets from applying themselves to the composition of real tragedy, and prevented the studious and judicious part of the public from frequenting the theatre. Moreover, Italy being divided into so many small states, never has had a great and
central point of union for Italian ambition. The Romans, the Lombards, the Tuscans, the Piedmontese, the Venetians, and the Neapolitans, considered each other as having different interests, and as enemies, or at least rivals, both in the sciences and in the fine arts.

Here Calsigbi dilates on the baneful effects of the opposition in schools of painting, a subject on which we are incapable of appreciating the truth of his remarks; but language being a more conventional way of imitating nature, than by objects addressed immediately to the sight, and intelligible to all men, it must clearly be much more affected in its progress towards refinement than either painting or sculpture, by the provincial distractions of an unsettled style. "This is the reason, (he continues) that having no permanent theatre, whilst in many cities there was a musical stage, almost constantly we have returned to this latter, forming dramatic monsters; for such are the greatest part of our musical plays."

In spite of all these disadvantages, Italy again rose into dramatic lustre in the eighteenth century. Goldoni redeemed the genius of its comedy, if not entirely from farce, at least to comparative refinement from its former state. Metastasio infused poetry into the opera, and Maffei delineated in his Merope, some of the strongest workings of the human heart. Some pieces of considerable interest appeared from the time of Maffei to that of Alfieri; but, upon the whole, the tragic genius of the country, seemed to be again sinking into languor, when that latter extraordinary genius (Alfieri) appeared. In him, the tragic muse spoke a language fraught with an elevation of sentiment, and a strength of majesty, of which her dramatic pieces had formerly conveyed no trace. With classical simplicity of structure, he sought to unite a stern and austere grandeur of diction, wholly unlike the conceits and effeminacy which had so long possessed his native stage. The universal feelings of his countrymen seemed to sympathise with his regenerating efforts; and the burst of public applause which they excited, seemed to say, that Italy had still majestic sentiments of virtue, to which the portraiture of her sickly drama had not before done justice. Even the partiality of his countrymen, however, was not blind to the errors into which his genius fell, from a systematic and overstrained pursuit of peculiar excellencies. The regularity of his first tragedies, was felt to border upon stiffness; his austerity of sentiment, on harshness; and the purity of his diction, on boldness and abrupt compression. In avoiding the florid luxury of his national poetry, he over-affected the sombre energy of Dante. At a subsequent period, he adopted the scripture subject of Saul; and it appears upon the whole, by its grandeur and primitive simplicity, to have accorded well with the tone of his genius. Probably instructed by public opinion, he now gave his thoughts a more poetical dress; there is even occasionally in this piece an oriental pomp of expression. The subject is the frenzy and death of the Hebrew monarch; the characters which attach our sympathy by their dangers and Pourtrayed affections, are those of Jonathan, David, and his beloved Micah. The reader, without being hypercritical, will regret in this beautiful tragedy, that the knot of interest is not sufficiently distinct and visible. We have a general alarm and presentiment of danger, from the menacing insanity of Saul; but the events to be hoped for or feared, are somewhat too undefined, and the curiosity is rather passively than actively exercised. But still the tone of the piece is inspired and enchanting. The beauty of the friendly characters fixes our love; the madness of Saul is a thrilling and terrible picture; and the proud, fanatical enthusiasm of Achimelech, when he denounces the curse of heaven on the king for his slaughter of the priests, contrasted with the severe intrepidity of Samuel, furnish scenes of the most profound and electrifying effect. To enter on the whole drama of Alfieri, would far surpass our limits; we must content ourselves with remarking, that in Vincenzo Monti, who, we believe, is still alive, Italy possesses a highly promising tragic poet, who, in his tragedies of Galezzino, Manfredi, and Aristodemus, has evinced a spirit worthy of succeeding Alfieri, and who, in the charms of diction, is supposed even to surpass him. The revival of poetry at so late a period, may well encourage us to expect, that a people whose genius has ever shone so conspicuous in the other arts, will yet enrich the world of fancy with captivating productions of the drama.

Among the nations of modern Europe, Spain commenced her career in literature more independently of strangers than any other. Dramatic poetry, in particular, sprung up among them, before the subsequent extension of their empire gave them any connection with their neighbours, and forming itself on the ancient Castilian taste, after their own manners, and customs, and romantic fancies, it was much less regular than that of other nations; much less imbued with the sage spirit which united philosophy with enthusiasm among the Greeks; but it was much more calculated to move the native Spaniard; much more in harmony with his opinions and feelings; and much more calculated to hold of his national pride. Such was its impression, that neither the satires of other nations, nor the criticisms of their own literary men, nor the prizes of academies, nor the favour of princes, have ever been able to bring the Spaniards into the dramatic system which predominates in the rest of Europe. Italy boasts of Tasso, in the 16th century, as the author of the first regular tragedy of modern Europe. Without a claim to regularity, the Spaniards go back to the 15th century for the birth of their dramatic poetry. They ascribe its origin to three works of a kind very different from one another, viz. the mysteries of the churches; the satirical and pastoral drama, entitled Mingo Rebulo; and the dramatic romance of Calixtus and Meliboea, or Celestina. The mysteries, which constituted the ornaments of their religious solemnities, had an indisputable influence on the Spanish theatres; and the Autos Sacramentales of their most celebrated authors, are made almost on the model of those ancient holy farces. The work called Mingo Rebulo, composed before the middle of the 15th century, under the reign of John II. and which was meant to turn the monarch and his court into ridicule, is rather a political satire in dialogue, than a drama. But the Celestina has very different claims to the attention of those who are curious about the origin of the modern drama. Of this strange piece, the first act was written by one whose name is unknown, about the middle of the 15th century, at a time when the rest of Europe was applauding the profane drollery of the mysteries, and long before any other people of modern Europe had shown the slightest talent for the comic drama. The dialogue of Celestina has frequently spirit, wit, and gaiety; the characters are tolerably traced;
and the intrigue exposed with sufficient clearness; and the language of the lovers supported with warmth and sensibility. But the first anonymous author had left the action incomplete; he had only interested us in the love which the beautiful Melibea had cherished for Calixtus; had apprised us of the obstacles which their passion opposed to their union; and had introduced to Calixtus a sorceress named Celestina, who had engaged to assist him in his love. Fernand de Rojas continued this imperfect comedy about the year 1510, and prolonged it to twenty acts; a length which precluded its representation. He makes the personages pass through the most romantic adventures, and gives the drama a tragic denouement. Celestina introduces herself into the house of Melibea, corrupts her domestics, bewitches the young woman by her spells, and brings her to guilt. Scarcely is Melibea plunged in dishonour, than her relations avenge it. The different domestics who had been employed by Celestina perish by the sword or poison; she herself is poignarded, Calixtus is also killed, and Melibea throws herself from the top of a tower. Thus, romance succeeds to comedy, and the interest of fancy to that of curiosity. In spite of this, few works have been greater national favourites than this of Celestina, whose enthusiastic admirers in Spain, have considered it as the first lesson of morality ever exhibited by the drama. There were many Spaniards, however, who thought its tendency very different. To decide the controversy, the church was consulted. The issue of this appeal was, that in Spain it was prohibited, in Italy approved—and it should be noticed, that in point of time, we are speaking of a tragic-comedy begun in 1440, finished in 1510; begun sixty and finished five years before the appearance of Trissino's Sophonisba, and yet of sufficient importance to divide the public opinion of Europe, and to have Italy on the side of the debated play. This circumstance shows, that the popularity of Spanish literature was more early and important than is generally supposed.

Such was the state of the Spanish theatre, pleasantly described by Cervantes, when Lope de Rueda, whose comedies and acting the author of Don Quixote had admired in his youth, headed his strolling company. His theatrical wealth, says Cervantes, consisted in four white shepherd's dresses, garnished with gilt feather, four beards and trains of false hair, and four crooks, more or less. The comedies were only conversations, like eclogues, between two or three shepherds and a shepherdess, which were embellished and prolonged by two or three interludes of Negresses, clowns, and Biscayans. Naharro, (says Cervantes,) a native of Toledo, succeeded to Lope de Rueda in celebrity as a comic actor and author. He made some small addition to the decorations of his native theatre, and changed the sack which had conveyed its moveables into boxes. He brought forward the music, which had been kept behind the curtain, in front of the scene, and took away the false and artificial beards from the performers, except from those who played the characters of old men. He was also the author of comedies, and light farces and battles, by artificial means on the stage. But nothing of this kind, Cervantes adds, was brought to perfection, until his own plays were performed; and he boasts of being the first who exhibited moral and allegorical figures in the Spanish theatre, as well as of reducing the representation from five to three acts. In this latter circumstance, however, Cervantes appears to have been ignorant, that Torres Naharro had anticipated him. The name of Cervantes himself forms an interesting epoch in the Spanish drama. He composed, he tells us, from twenty to thirty comedies. (The word comedy was at this time applied, in a very strange manner, to productions fraught with representations of the terrible and pathetic.)

—Lope de Vega possessed a lively and magic volubility, for rendering absurdity itself entertaining. Cervantes was no more than his great contemporary, seriously disposed to give a classical harmony of design to the Spanish drama. They both of them laughed at their own inferiority to the ancients, and Lope even speaks of his preparing himself for the composition, by putting the ancient authors out of his study, lest they should chill him by their condemnation; but both he and Cervantes were probably, in their own predilection, as much disposed to the fantastic drama, as their audience were exclusively disposed to receive it. Lope succeeded, and Cervantes, we find, was comparatively unfortunate. No great weight needs to be attached to the decision of their contemporaries, if we consider a tasteless and barbarous age as standing upreight between them. But whatever the genius of the Spanish drama might be, Lope de Vega contrived to make it popular, while the nervous precision of thought, and the solid talent of Cervantes, seems to have been ill calculated to deal with its mass of intrigues and adventures. His comedies are therefore, in general, (and it would seem with great justice) accused of being cold and fatiguing; and in the dispute between this great man and the contemporary public, respecting the degree of his dramatic genius, the public opinion, which rated it lower than he did himself, appears in this, as in most cases of the same kind, to be right.†

There is nevertheless one of his early pieces, written before his rivalry with Lope de Vega began, which may well qualify any general decision against his talents for the drama;—this is his tragedy on the siege of Numantia. It is altogether a distracting medley

* It was probably owing to this want of a regular theatre in Spain, that the pieces of Torres, a comic poet anterior to Lope de Rueda, and who, though not mentioned by Cervantes, was really the father of Spanish comedy, never were acted in his native country; at least there is no proof that they were acted, although to Bouterwek they were printed as early as 1533. Torres Naharro is also supposed to be the first who divided Spanish comedy into three acts or jornadas. It does not even appear that Torres Naharro's pieces were ever popular, for they were immediately forgotten in the reputation of those prose comedies of Lope de Rueda, which Cervantes speaks of having seen in his youth. Torres Naharro is to be distinguished from another Naharro, who is mentioned by Cervantes as the successor of Rueda in reputation for comic compositions and acting. Without finding it possible to enter individually into the merits of those who commenced the career of the Spanish drama, it would be injustice, even in the shortest sketch, to omit the name of Gerónimo Bermúdez. This writer was a Dominican of Galicia, who was so diffident, that he would not venture to publish at first, but under a feigned name. He is the author of two tragedies on the subject of Inez de Castro; one of which contains some passages highly tragic and elevated. Taken altogether, his tragic poetry is poor and imperfect; but his taste is entitled to respect for the attempt which he made to give a classical turn, and an elevated tone of diction, to the language of tragedy; an example on which so few dramatic writers of his country thought fit to improve. Had there been but one or two men of genius to follow the hint of Bermúdez, the Spanish stage would not have been disgraced by the wild extravagance of its general character. This old Dominican, as his genius was, saw with the eye of taste, that while the classical form of tragedy was desirable, the accidental, the subjects of modern interest were fitted for a modern stage. He chose, therefore, the subject of the unfortunate Inez de Castro, which Camoens has made poetically memorable, by embodying it in the Lusíad; but Gerónimo Bermúdez wrote before the Lusíad had appeared.

† It is generally allowed, however, that the interludes, or short comedies of Cervantes, possess considerable merit.
of great absurdities; and at the same time of sublime and impressive traits of imagination. To uphold it altogether as a good or a great tragedy, is impossible; but it is equally impossible to deny, that it must remind every reader of Æschylus, of those gigantic traits of terror, which distinguish the father of Greek tragedy. It fairly challenges a comparison with Æschylus's Persians, or the Seven Chiefs of Thebes, in the boldness of its pictures, and grandeur of execution, and justifies what an able critic has said, that its author, in more favourable circumstances, would have become the Æschylus of Spain. As Cervantes found but a very few facts in the historians who relate the destruction of Numantia, he was obliged to invent most of the incidents of the piece. His object was to unite the marvellous and pathetic; and though the story of a siege, in which the inhabitants determined at last to destroy themselves, and to perish in the flaming ruins of the place, rather than submit, is not what we should consider, in the present day, as a subject best fitted for dramatic effect: yet the mind cannot but sympathise with the zeal and patriotism which a poet must have felt in endeavouring to record such terrific grandeur in the national character. The scene opens with the Roman camp, which is before Numantia. Æsculapius appears with his principal officers, and addresses his soldiers, to reprimand them for their sloth and luxury, which has delayed the conclusion of the siege. The address, though long, is full of Roman and soldier-like eloquence. In this scene, the novelty of the dramatic art is pleasantly developed in the notes of direction which the author gives to his actors. Here there shall enter as many soldiers as can be brought upon the stage, and Cainis Marius with them; they shall be armed in the ancient manner, without firelocks; and Scipio, mounted upon a small rock, which shall be upon the stage, shall look at his soldiers before addressing them. Numantian ambassadors arrive with offers of peace, which Scipio rejects. Spain is then personified, and appears upon the stage as a female, crowned with towers, and bearing a castle in her hand, in allusion to the name of Castile. She calls for the rivers Duero, or Durius, on the banks of which Numantia was situated; and Duero presents himself, accompanied by three tributary streams. These allegories may make us smile, while they remind us of the appearance of the Thames, in Sheridan's critique, between two attendants, representing his banks, with willows in their hands.—But we should also recollect, that if classical example can palliate the circumstance, Euripides has his character of Xanthus, or death, a principal agent in the drama of Alcestes, not to mention the allegorical personages whom Æschylus brings to light—Prometheus. After Spain and the river gods have consulted about the fate of the city, the scene changes, and transports us to Numantia;—the senate is assembled, and deliberates on the common danger. In the second act, a commencing interest is created in the character of a young Numantian, Morandro, the lover of Lira; and a story of individual and tender passion is therefore interwoven with the history of the siege. A scene of public sacrifice ensues, in which the terrors of the people are aggravated by unfavourable omens; the torches will not kindle their fire, and the thunder sounds an evil presage, in answer to the sacred invocations. (Here another note of the author directs the actors to imitate thunder, by hurling under the stage a tumbrel, or vessel full of stones.) At last the victim is snatched from the sacrifice by an infernal spirit. So much of the effect of such scenes depends on execution, that it is difficult to say how much of the ludicrous or of the terrible might predominate, according to circumstances, in their representation. —But a scene ensues, in which, though there is some degree of the horrible, there is also so much intrinsic terror, that we might conceive it to be highly effective, even with ordinary apparatus. —This is, when the sacrifice having failed, recourse is had to a magician, who is gifted by his enchantments to predict the will of heaven. He approaches the tomb of one who had recently died of famine, and invokes the spirit from the realms of death. His address to the infernal powers is highly poetical. He speaks to the demons in that tone of command, and even with that wrathful disdain, which fiction ascribes to the magicians that are the masters, not the subjects, of infernal influence.—The tomb opens—the body arises, but at first motionless and dead, till the magician forces it, by new enchantments, to assume animation and speech. The corpse then announces that Numantia shall not be conquered; but that it shall not be victorious; and that all its citizens shall perish by the sword upon one another;—it falls back again into the tomb, and the magician, in despair, plunges a weapon into his own breast, and buries himself in the same tomb. After the return of a second embassy, as fruitless as the first, the Numantians take up the resolution with which their heroic senator Theogenes inspires them, to burn with the pomp of a sacrifice all their precious effects—to put to death their women and children, and, lastly, to throw themselves into the funeral pile of ruin, that not one may survive to be a slave of the Romans. From the moment that this is determined, the author crowds together, till the conclusion, the deepest scenes of grief, and the most sublime traits of patriotism. Famine desolates the city. —The young lover and hero, Morandro, already mentioned, accompanied by a friend, penetrates into the Roman camp—he returns mortally wounded, but in possession of a piece of bread, which he has ravished, at the price of his life, from the enemy, in order to bring to his mistress Lira. He tells her, that the blood which stains the bread is his own, and expires at her feet, as he bequeaths the sad and bitter nourishment.

Pero mi sangre vertida
Y con esto pan devorado,
Je ha de dar, mi dote amada,
Triste et amarga comida.

The action supports itself with the same interest to the end of the piece, when Fame proclaims its conclusion from the ruins of Numantia, and predicts the future glory of Spain.

Lope Felix de Vega Corpio, was 15 years younger than Cervantes, being born in 1502. This prodigy of Vega's fertile talent, if he did not create the Spanish drama, at least unchangeably fixed its general character and form. So much did he establish the character of his native stage, for a century and a half to come, that to give an idea of his works, is, in some degree, to give an account of the subdivisions of the Spanish drama, and the character of each subdivision. The word comedy (comedía) in the language of the Spanish theatre, means something very different from what was so called by the Greeks and Romans, or what it still signifies over the greater part of Europe. It is a general name, comprehending several different kinds of dramatic composition, each of which is really neither tragedies nor comedies. The principle of the ancient comedy, and
of the modern comedy, properly so called, is deeply connected with moral satire. In the Spanish comedy, satire is purely accessory and contingent. The portraiture of character is essential to the regular comedy of the rest of polished Europe; but it is not essential to that of Spain. The object is incident, intrigue, and surprise; a hardy and careless pursuit of the imagination, after such a change of scenes, interspersing the pathetic and burlesque, the trivial and the marvellous, as may keep the attention busy, curious, and astonished. Such a state of mind is obviously inconsistent with the pleasure arising from what we call comedy; in which the draught of manners is perhaps the first requisite, and wit and satire the second. But an interesting exhibition of manners requires a clear probability of incident; and the enjoyment of moral satire requires, not a hurried and tumultuous, but a well connected and consistent flow of events; leaving the mind room to reflect on the past, as well as to conjecture respecting the future.

Since the time of Lope de Vega, it has been usual to distinguish the pieces of the Spanish theatre into two great classes,—comedies sacred or spiritual, and comedies profane, or belonging to human life. (Comedias divinas et humanas.) It is usual to divide this latter class of human-life comedies, into those which are called heroic, and those denominated the comedies of the cloak and sword, (Comedias de Capa y Espada.) The heroic comedies were in their origin confounded with those of history; and the name of heroic was extended to those founded on mythological subjects. Those comedies of the cloak and sword were also called Comedias de Figaro, because the principal personages of these pieces is generally a knight of industry, who gives himself out for a great lord, or a fine lady, who makes similar pretensions. The spiritual comedies have been also subdivided, since the time of Lope de Vega, into dramas drawn from the lives of the saints, (Vidas de Santos,) and into pieces of the holy sacrament, (Autos Sacramentales;) the former have been formed upon the model of pieces called lives of the saints, which used to be represented in the monasteries. The Autos Sacramentales seem to have arisen in the time of Lope de Vega. Finally, we must add to those different kinds of Spanish comedy, the interludes which are played between the prologue and the piece, and which used to be called Sigmeter, until they were mixed with dancing and music. The historical or heroic comedies of Lope de Vega are very numerous. The tragic scenes which were incorporated in those wild compositions, were adapted to the Spaniards for the want of real tragedies. Very few of those heroic dramas of Lope de Vega are drawn from foreign histories. His Gera de Don Quijote is of this small number. There is little difference of character in the vast variety which he produced. The unity of action is only apparent; and as to unity of place and time, Lope de Vega never thought of them. The style is as capricious as possible, sometimes extremely elegant, but falling again into laxness and common-place. To give some idea of those pieces, we shall give a very abridged extract of one of the best, which is called "The Fortress of Toro," Las Almejías de Toro. The subject is, the assassination of the King De Sancho, by Bellido a knight, whom the king had offended by breaking his word to him. The same subject has furnished the subject of several old romances. In this, as in these old romances, the Cid Ray Diaz plays an important part. The Cid, the Cid, and the Count Azares, appear first upon the scene, which represents a plain at the foot of the strong city of Toro, in the kingdom of Leon. The king declares to the two knights, that political reasons do not permit him to respect the testament of his father; and that he cannot leave his two sisters, Elvira and Urra, in possession of the two strong cities of Zamora and Toro. The Cid, with a generous liberty, represents to the King the injustice of his enterprise, and offers his mediation with Elvira. The King and the Count Azares withdraw, and the Cid approaches to the walls of the fortress. He meets the Chevalier Ordonez, who had stolen out of the city with the design of rendering some service to the Princess Elvira. The two knights at first prepare for battle; but, at the name of the Cid, Ordonez kisses his sword, and they both embrace. The Cid here shows himself in all the greatness of his character. The Infanta comes to speak to him from the top of the walls, and explains to him the reasons that have obliged her to shut the gates of the city against her brother. The King returns, and orders an assault to be made on the fortress. The scene changes. Don Vela, an ancient cavalier retired from the world, walks in front of his country-house, and makes a soliloquy. His daughter, who is young and beautiful, enters on the stage singing, and surrounded by a troop of villagers. With this scene commences the episode, or underplot of the piece, of which Don Vela is a Prince of Burgundy disguised as a peasant, and in love with Sandea, the daughter of Don Vela. The scene again changes to the walls of Toro. Negotiations are set on foot between the parties, and the King has an interview with his sister. The conversion, which is pretty well seasoned with abuse, and in which there is a great deal of quibbling on the double meaning of Toro, which signifies both a bull and the city besieged, produces no reconciliation. A second assault is made, and is repelled, which closes the first act. In the second act, the underplot of the disguised Prince of Burgundy begins to have some connection with the main action. The Prince, and the beautiful Sandea, mutually breathe their tenderness in sonnets. Don Bellido next appears. He promises the king to make him master of the fortress, if he will agree as a recompense to give him the hand of the Princess Elvira. The King promises this, and Don Bellido, by the basest act of treachery, puts him in possession of the fortress; but the king conceives himself justified in breaking his word with a traitor, and refuses him his sister. This unfortunate Princess escapes in the habit of a female peasant. She finds an asylum in the family of Don Vela; and the piece continues in this manner to alternate tender and heroic, domestic and rural scenes, till its denouement, which consists in the King being assassinated by Bellido, and the Infanta brought back in triumph to Toro. The piece concludes with the marriage of the beautiful Sandea to her Prince of Burgundy, and with the union of the Infanta to the traitor Bellido, who had assassinated her brother.

The comedies of the cloak and sword, or the comedies of intrigue of Lope de Vega, are not, it is true, plays of character, but they present pictures of manners drawn after the life, however romantic. Their style, though in verse, has the same inequality, and the general character of their plots is the same with that of the heroic ones. The scenes succeed each other, without the connection of cause or probable motives. All the writer's object is intrigue; and frequently the plot gets so intricate, that the poet is obliged to cut the knot of interest, which he cannot unclose. The plays of our author are generally strewed with reflections and maxims of prudence; but, Lope de Vega's comedies of the cloak and sword.
he would have thought himself abridging his own dramatic liberty, if he had introduced morality properly so called. He has wished to draw the manners of his countrymen such as he saw them, not such as they ought to have been, and he has left it to the spectators to draw a moral for themselves. The most licentious spirit of gallantry, coloured by a sort of decency, and feebly restrained by honour, but never by a sense of duty, constitutes the essence of his comedies. If the poet exhibits lively passions, they rush to their gratification with a vehemence truly Spanish; if he paints the sober and sentimental affections, they are breathed with inexhaustible tediousness, and conveyed in language full of quibble and affectation. That love excuses everything, was then the favourite maxim of good company in Spain, and the personsage of Lope de Vega, ladies as well as gentlemen, act quite conformably to the maxim. Treasons and rascalitys the most detestable are introduced as things of course, and murder is by no means rare. On the slightest occasion, men of rank draw their swords, and, if one or other is killed, it is hardly spoken of. In this species of his pieces, it is however confessed, that there reigns a great deal of the natural, and that its expression never injures his poetical colouring. Of this description of his pieces, the Widow of Valencia (La Viuda de Valencia) forms an unfavourable example, as the plot is well supported, and as it has the rare merit of unity of action. The scene is laid at Valencia in the time of the carnival. Leonarda, a young, beautiful, and rich widow, but very capricious, has formed the resolution of never marrying again. She comes on the stage with a book in her hand, and tells us, that though she is neither a devotee nor a bel esprit, she reads for her amusement both profane and devout books, and that she desigs not to honour with a look the swarm of adorers who persecute her. After a great many spirited and sage remarks, which the widow makes on the vanity of admiration, her righous waiting-woman contrives to make her conclude them before a mirror, and in this situation she is found to her great mortification by her uncle. The old gentleman, however, consoles her, by proving the utility of looking-glasses, and advises her to a second marriage. In reply to which, she expatiates on the consequences of rash engagements, and with great pleasantry draws the picture of a man of fashion of Madrid in the 16th century. The uncle leaves her, and the scene changes. Three of the lovely widow's admirers present themselves before her gates, and each of them expresses, in a sonnet of one prolonged metaphor, their secret wishes and hopes. As they have no occasion to congratulate each other on the kindness of their mistress, they make a common confidence, and each relates a burlesque adventure, which had happened to him that night before the mansion of Leonarda. Leonarda, however, returns from the church in great haste, for she had seen a young man for whom she had conceived a passion, which altered her views about marriage. She wishes to bring him to her house, but resolves that he shall be ignorant whose it is. Her coachman Urbano, who is also the gracioso or buffoon of the piece, is charged with this commission. He goes off to fill it, and in the meantime the three lovers arrive masked, but without design, in the same manner. They are disguised as hawkers of books and prints. Their reception and dismissal by Leonarda has considerable gaiety. In the second act, the favourite youth Camillus makes his appearance, and hesitates for a long time whether to hazard the adventure which is proposed to him. Urbano draws a doctor's cap (capriote) over his eyes, and brings him thus, after a great many windings and turnings, to the apartment of Leonarda. She is masked. A magnificent collation is served up, of which the young man scarcely dares to taste, in his fears for the possible consequences of his adventure; whilst he compares himself to Alexander about to swallow the suspected beverage from his physician. After a tender interview, the doctor's cap is replaced over his eyes, and he is taken home. Several days are supposed to be passed over in one scene after another, in the course of which the decency of the widow's conduct is far from being ir reproachable. At length, after many singular changes and incidents, chance unravels the plot, after the author, as a passing amusement, has made a fair and honourable lover of the widow to be killed by the sword. Camillus finds the fair unknown one to be a beauty whom he had long admired, and is very happy to become her husband.

The spiritual comedies of Lope de Vega, pourray the religion of his times as faithfully as his comedies of intrigue point its manners. A true piety in the old Catholic sense, strangely founded in the most absurd chimeras; but chimeras often, ennobled by the genius of a bold and strong poetry, presents us with a creation unlike any other species of composition. The mixture of poetry, however, is very different in different pieces of this theological drama. Those, of which the subject is taken from the lives of the saints, have much more poetry than the comedies of the holy sacrament. Both of them were represented with great pomp, machinery, and music; in fact, with all the apparatus of the genuine opera. Of all his pieces, his Lives of the Saints are the most irregular. In these are introduced promiscuously, buffoons, saints, allegorical personages, peasants, kings, students, the infant Jesus, the eternal Father, the devil, and all that heterogeneous fancy could bring together. In the comedy of St Nicholas of Tolentino, (a modern saint, whom Lope has made the hero of one of his spiritual pieces,) the scene opens by a conversation of students, who emulously bring forward their wit, and scholastic erudition. Among these theologians, is the future saint; and his piety shines greatly in this society, which is a little profane. The devil, who is prudently masked, mixes himself with the comedy. A skeleton appears in the air. The heavens open, and the eternal Father is seen seated on his tribunal between Justice and Mercy, who alternately make their remonstrances to him. To this scene another succeeds, which makes us acquainted with a love intrigue between a Dame Rosalie and a Don Feniso. The saint again appears, and makes a sermon in Redondela verses. Having already become a canon, his parents testify their joy at having such a son; and thus ends the first act. In the second act, the saint prays in the shape of a sonnet; the heavens are opened, and he is taken up thither by the power of faith. He reappears, however, and the devil comes to tempt him. A little afterwards, there is a view of purgatory, and the souls which are roasting therein. The devil returns with a number of serpents, lions, and other frightful animals; but a religious person of the convent chases him off with a huge besom, in a scene which the author purposely makes burlesque (graciosamente.)

The autos, or comedies of the holy sacrament, were sufficiently absurd, but more simple and serious; in texture, more full of theological discussion, and so full of allegory and divinity, that it is difficult to conceive their having been intelligible to the common people: But the prologues and the interludes (Extremeses y synynter) appear to have been intended as
a compensation to the mob for the dullness of the autos. The intermedes are burlesque from beginning to end. This description of farces, taken entirely from the sphere of common life, was so popular in Spain, that no piece could be brought on the stage without one of them to recommend it. To sum up the dramatic character of Lope de Vega, we shall only quote the words of Lord Holland from his life of the poet. "The most temperate critics, while they acknowledge his defects, pay a just tribute of admiration to the fertility of his invention, the happiness of his expressions, and the purity of his diction. All agree that his genius reflects honour on his country, though some may be disposed to question the influence of his works on the taste and literature of their nation. Indeed, his careless and easy mode of writing made as many poets as poems. He so familiarised his countrymen with the mechanism of verse, he supplied them with such a store of common-place images and epithets, he coined such a variety of convenient expressions, that the very facility of versification seems to have prevented the effusions of genius, and the redundancy of poetical phrases to have superseded all originality of language. But the effect of Lope's labours must not be considered by a reference to language alone. For the general interest of dramatic productions, for the variety and spirit of the dialogue, as well as for some particular plays, all modern theatres, are indebted to him. Perfection in any art is only to be attained by successive improvement; and though the last polish often effaces the marks of the preceding workman, his skill was not less necessary to the accomplishment of the work, than the hand of his more celebrated successor. Had Lope never written, the master-pieces of Corneille and Moliere might never have been produced; and were not these celebrated compositions known, he might still be regarded as one of the best dramatic authors of Europe." Life of Lope de Vega, p. 229. et seq.

Pedro Calderon.

The name of Pedro Calderon forms the next great epoch in the history of the Spanish drama. His countrymen generally consider him as the sovereign genius of their stage; and some German critics have attempted to place him at the head of all modern dramatists. The number of tragedies, comedies, and farces, which he composed, has been differently estimated; but all accounts agree in representing them as exceedingly numerous. A most eloquent elogio on this writer has been given by the celebrated Mr Schlegel, a part of which has appeared in the last work of Madame de Stael. Even those who go not so far as Mr Schlegel in idolizing his genius, seem to agree to his general superiority over Lope de Vega himself, in combination of plot, in imbroglios, and in the invention of interesting situations. The palmer of fiction invention seems to be universally accorded to him; and with art and taste, whether in plan, execution, or style, it may be said that he created a new species of comedy. An air of delicacy and dignity breathes in his heroic pieces a higher strain of sentiment; and though the Spanish stage is, from its rapid intrigue, unsuited to the display of character, yet amidst the complexity and whirl of its action, he is allowed to produce traits of character which frequently give a deep insight into the hearts of his personages. A lively and bewitching dialogue, a delicious versification, and a subtilety almost inconceivable, in the nature of his plots, are the merits which his admirers challenge for him, above all other poets of the modern world. This merit of ingenious contrivance of plot, is indeed with him, and the most of Spanish writers, carried to a degree which a northern temperment has not curiosity to follow. The interest which many Spanish plots excite, is so labyrinthical, that the comprehension of them becomes a fatigue. But in this case, we must consider a poet as addressing himself to his countrymen; and the mind of a Spaniard, whether from an idler life, that gives him more practice in aerial castle-building, or from an imagination constitutionally more ardent, which invigorates his memory, has an easy delight in pursuing a dramatic story, which, to an Englishman or a Frenchman, would be wholly unintelligible. We are told by a credible traveller, that all Spaniards, without distinction, are so expert in following the thread of a plot, in its subtlest ramifications, that a common spectator, after having seen a piece performed, will repeat to you its whole contents in detail, while an intelligent stranger, the most familiarly acquainted with their language, can scarcely connect in his comprehension a few of the scenes. It is confessed, however, by judges, who, if they are far inferior to Mr Schlegel in the eloquence of enthusiasm, are no less intimately acquainted with the extensive drama of Calderon, (in itself the study of half a lifetime), that though he has the greatest talent in accumulating surprises, in linking together the most interesting situations, and in keeping curiosity alive, he is even less careful than Lope himself to connect his scenes with probability, or in giving motives and necessity to the entrance and exits of his personages. Even while the harmony of versification is admitted, sufficient proofs have been extracted by the critics, who have viewed him less favourably, that his finest pieces abound with monstrous deprivations of style, to which the conceits of the Italians is comparative simplicity. Calderon lived at the miserable epoch of Philip IV., and in his works there often breathes a ferocity of religious fanaticism which is truly horrible. One of his pieces is entitled "The Devotion of the Cross." The object of it was, to convince all Christian spectators, that devotion for the standard of the church suffices to atone for all crimes, and to insure the protection of God. "The hero is an artist, a blighter, an assassin by profession, but who raises the cross as an expiation for all his atrocities, on the tombs of each of his victims. The heroine, Julia, who is at once his sister and his mistress, more abandoned and more ferocious, if possible, than himself, participates in the same devotion for the sacred sign. He is finally killed in a conflict which he maintains against the troops of his own father; but he is raised from the dead, that a religious saint may hear his confession, and also assure his reception into heaven. His sister, when on the point of being taken, and made a victim to her enormities, embraces a cross which she finds before her, and makes a vow to return to a convent, and mourn for her transgressions. This cross immediately raises her up in the air, and carries her away, far from his enemies, to an impenetrable asylum. By those who have compared his voluminous pieces, that of his tragedy of Don Fernand is said to be the one in which he has put forth the greatest power of his genius. The Spanish title is "El Principe Constante." The unities of time and place are not observed; and, what is still worse, the unity of action, though preserved to a certain length, is ultimately violated. But as far as that unity goes, the story is greatly interesting and affecting. Don Fernand, Prince of Portugal, makes a descent upon the coast of Africa, accompanied by his brother Don Henry. He attacks the states of the King of Morocco, and is conqueror in the first battle, in
which an African hero. Muley, is made prisoner. This
Muley, who is in love with the daughter of the King
of Morocco, relates his history to the Prince of Portu-
gal; and Fernand, whose generosity is moved by the
recait, sets his captive at liberty. Scarcely has Muley
had time to express his surprise and his gratitude,
when reinforcements arriving to the Moorish army, a
second battle ensues, in which Fernand is defeated,
and in his turn taken prisoner. Here commences the
tragic interest, which is prepared by touching situa-
tions of a gentler description. The King of Morocco
offers liberty to his prisoner in exchange for the for-
tress of Ceuta, which the Portuguese possessed upon
his coasts. But the Prince declares that he will rather
in the cruellest slavery, than see a Christian deliv-
ered for his sake into the power of the infidels.
The Moorish sovereign sends an embassy to Portugal to re-
new the offer, which he thought the subjects of Fer-
nand could not refuse. They agree, indeed, to it, but
the heroic Prince still refuses his liberty on such terms.
Enraged at this refusal, the infidels aggravate his mis-
series, and subject him to the torture; but his constan-
cy is proof against them all. In the mean time, the
heart of Muley is bursting with agony at beholding the
sufferings of his former deliverer. The Moorish Prin-
cess, who returns Muley’s love, is also deeply interest-
ed in behalf of the Christian Prince. They plead in
vain for him; and a deeper shade of melancholy in-
terest is spread over this unfortunate pair in being torn
from each other. Their history, it is true, is in some
degree episodical, and independent of Fernand’s his-
tory; but still it is chained to it by an unity which
the mind forms to itself in considering them as the only
friends of the hero in a barbarous foreign country.
Fernand dies an unyielding martyr—the Regulus of
his country. And here, it must be confessed, the uni-
ty of action ceases; but the story is prolonged by the
arrival of a fresh army from Portugal. The scene of
it should be posthumous and disjointed, however
in itself imposing. It is the dead of night—military
music is heard at a distance—it approaches, and the
ghost of the martyr arrives with a torch in his hand,
and appears conducting the Christian troops against
the walls of Fez. Don Alphonso, the living leader of
the ‘warriors of Portugal, calls the King of Morocco to a
parley, tells him that he has killed his daughter Pheni-
cia, and her lover, the generous Muley, himself.
A treaty is concluded, by which the corpse of Fernand
is restored in return for the Moorish Princess and Mu-
ley; and the Christians obtain as a stipulation, that
they shall be suffered to marry her as a reward for their
common affection towards the dead Fernand.

Amidst those great names which constitute epochs in
the Spanish drama, we have forborne to speak of sev-
everal intermediate writers, who, although generally their
imitators, might probably, in some instance, improve
upon their models; but to give a list of all the drama-
tic writers of this theatre, would be to encroach too se-
iously on the boundaries of any Encyclopaedia. Among
the writers of the genuine Spanish school, who suc-
cceeded Calderon, are Antonio de Solis, and Augustia
Moreto. The former has paid great attention to give va-
riety to his comic characters, a circumstance in which
Calderon himself was deficient—, the latter is really the
most truly comic of all Spanish writers. Many others
might be mentioned, as Juan de Hoz, Tisso de Mol-
a, and the Chevalier Francisco de Rojas, or Rosas,
and Guillen de Castro, from whose pieces it is to be
hoped that a selection will yet be formed, sufficient-
ly worthy of the national honour; for in the editions
of the Spanish poets, the fault has been to make collec-
tions, of which many pieces are falsely attributed to
great names, instead of making selections of what is
intrinsically valuable. The facility of style in which
Lope de Vega and the primitive authoresses indulged, is
justly remarked by Lord Holland to have, in all prob-
ability, given rise to the revolution in taste and style,
which took place in the latter part of the century.
This revolution consisted in passing from the extremes
of licence, and simple carelessness, to that manner of
artificial bombast which is, in Spanish literature, called
Gongarism, from the author Gongora, who first brought
it into fashion.

This obscure and inflated school of writers seems,
however, at no time to have had possession of the
stage. Another revolution was approaching at the
commencement of the eighteenth century, which, for
a time, was scarcely less fatal. This was the influ-
ence of French taste, which, in the age of Louis XIV.
was extended all over Europe. Even in the 18th century,
it is true Spain has to boast of the names of Candomo
La Mora, and Canizares, who were the last of the school
of Calderon. But the influence of a foreign taste began to be sensibly felt when Luzan
published his Art of Poetry; and while he allowed no in-
considerable portion of genius to the great dramatic
names of his country, yet measured their merits so
strictly by the code of Aristotle and Horace, that he
left them, as far as his cold verdict extended, only the
shadow of their fame. When we express ourselves
with this apparent partiality for the old Spanish drama
which was thus attacked, we wish by no means to be
understood to be its implicit advocates. It is only from
a conception that the critical code of one nation is not
to be coldly or rashly applied to the poetical practice of
another. The French writers have a system of beau-
ties in their style and execution, which cannot be made
a standard without abundant qualification to the poe-
try of any people but themselves; and it would be
equally absurd to demand, in a French tragedy, the
same romantic traits which a Spanish tragedy possesses,
or to expect, in the works of Lope de Vega or of Cal-
deron, the entire regularity of Racine or Voltaire.
With regard to Luzan the critic, (a poet who was the
apostle of the Gallician taste), his system of poetical
criticism is in its essence and principles utterly cold
and bad. He was a pedant in the strict spirit and sense
of the word; and while he maintained that the natu-
ral, the useful or moral, and the elegant, were the fun-
damental principles of poetry, he was totally blind to
irregular inspiration of genius, so often displayed by
his countrymen, in which the beautiful rises above ele-
gance and correctness, and in which morality and senti-
ment, however noble and true, is not to be submitted
to the frigid rules of logical calculation. For half a
century, more or less, the Spaniards submitted to hear
their ancient and once boasted authors criticised with
indignity, till at last the plays written, or pretended
were to be written, on the system of French elegance, though
the true spirit of French tragedy was in reality far from
them, cured the nation of this predilection more effec-
tually than any critical dissertations of this taste for
taste correctness and Gallicism.

About the commencement of the latter part of the
18th century, Vincent Garcia de la Huerta dared to
raise his voice against the fashion and the learning,
which undervalued the primitive dramatic school of his
country. His poetical reputation, and some tragedies
which he wrote, made him a formidable antagonist of the Gallicists; and since that time, the turn of public opinion in Europe has been certainly rather against, than in favour of the poetical system which he attacked. It cannot be disguised, however, that Huerta, who avowed himself the advocate of the ancient Spanish poets, and who was one of the first of our national critics, appears as if, in spite of himself, the imitator of the French poets in his practice, and has even accommodated the Zaire of Voltaire to the Spanish theatre.

It is singular, that, as far back as during the reign of the mysteries and moralities, the French language should have to boast of more than one very good farce. The Avocat Patelin, which has really a humorous and well-conducted plot, is supposed by Fontenelle to be as old as the time of Louis XII. Another, entitled, "Les morts vivants," which has also a great deal of pleasantry, is as old as the 16th century. But the genuine French drama, after some regular, but feeble attempts at tragedy, by Jodelle, Mairet, Hardi, Rotrae, and a few others, can only be said to have commenced with Corneille. As a critique on this writer has been already given in our work, we shall content ourselves with referring to that article, and proceed to consider the character of their successors, Racine, Voltaire, and Crebillon, who have since carried the French tragic drama to all the perfection of which it appears to be susceptible, consistently with the narrow and limiting principles by which it is guided. Racine, without the pomp and ambitious conceptions of Corneille, is at the same time free from his turgidity. None of his plots have the bold and natural variety of action, which charms us in the drama of Shakespeare; but his art in arranging, opening, and thickening a plot, is that of a master. Such also is his skill in the management of his scenes, in adding to the embarrassment and increasing the interest of the piece; and his felicity in never leaving the stage empty, or occupied by characters brought on for the sole purpose of filling it. In his language, there is delicacy, purity, and harmony. A simplicity noble, but not ostentatious. A style at once judicious and beautiful, which, without appearing to feel the fetters of rhyme, expresses at once the fiercest declamatory passions, and the subtilities of moral reasoning. The perfection of his language is so great, that all his excellence is lost in representation. His pieces are highly finished, and exquisite pictures, which, to discover their full excellence, must be inspected at leisure, and with reflection. The shades of his bewitching poetry, according to the critics of his own country, (who, in point of style at least, are best entitled to judge of him,) are so delicate, that it is difficult to find actors capable of conceiving and expressing them. The strongest things that can be said to the detriment of Racine's merit, seem to apply rather to the cast of his national drama, and to the language in which he wrote, than to his own genius. The language in which he wrote is unfit for blank verse, and, by the bondage of rhyme, must of necessity give a narrowed and straitened expression to the utterance of passion. The severe dogmas of esthetic grammar chained him to the unities, as far as it was possible to observe them. It may be fairly said, that, without altering the genius of the French stage, if not of their language, it is impossible to reach a finer or more affecting and natural tone of poetry, than that which breathes throughout his Phedra and Berenice.

graces are like those of a cultivated landscape; while those of Shakespeare are like the views of a vast wilderness, interspersing horrors with exuberance of sweets. His own countrymen have objected monotony of character and sentiment to Racine; but this charge, at least in comparison with Corneille, appears to be frivolous. It is really Corneille who may be accused of too much uniformity. In Corneille's pieces, the names alone are varied. The characters and passions are the same. The sentiments are alike in all. Haughtiness, pretended Roman magnanimity, sometimes swelled to a gigantic size, are constantly the prevailing features; and desire of revenge frequently too atrocious for nature. Of six or seven pieces of Corneille which are in representation, this unnatural spirit of revenge is the ground-work of four; the Cid, Cinna, Rodogune, and the death of Pompey. Chimene, Corcelia, and Emilia, all demand the punishment of a father or a husband; and the abominable Cleopatra, in Rodogune, enumerates revenge, among her pretences for the horrors which she mediates. Racine would have probably diversified his theatre much more, had he not renounced the exercise of his genius when it had attained its full vigour. Britannicus, Iphigenia, Bajazet, Phaedra, Athalie, have no common similitude to each other. He has delineated but few passions, because he wrote but few pieces. His disgust at the criticisms of a finical age, co-operating with some superstitious scruples about the moral effects of the stage, unhappily consigned him to inactivity.

Voltaire aspired to an original manner in his native drama, by giving a greater variety and multiplicity of portraits to it, than are found in either Corneille or Racine. Far inferior to Racine in beauty of expression and style, and without those touches of sentiment and tenderness, which win the heart in that author, he has introduced a greater variety of human manners and situations on the stage, than any of his native predecessors. In A†ira, the customs of America are opposed to those of Europe. In the Orphan of China, the virtues of a civilized people are contrasted with the violence of barbarians. In Tancred, there is a display of the pomp and circumstance of chivalry. The intrigues and crimes of courts are unveiled in Semiramis.—He adds to this merit, that of a highly philanthropic and philosophical strain of sentiment. In Voltaire's theatre, there are no gratuitous horrors—no straining at the sublime by detestable accumulations of enormity. In this respect, both Voltaire and Racine stand respectively in comparison with Corneille, and with Crebillon, who, appearing as a competitor with Voltaire, was for a time upheld in the opinion of a giddy public, by some horrible tragedies, now justly fallen into oblivion. The secret of tragedy, Crebillon seems to have believed to consist in inventing monsters of villany. In his A†re et Thyeste, he superadds to the guilt which the Greek fable ascribes to the sons of Tantalus, contrives a plot of a double paricide, and concludes the piece, by making a villain declare that he now enjoys the fruit of all his crimes. The French tragic drama is professedly founded on the principles of the ancient Greek tragedy.

Without detaining the reader with any dissertation on the topic subject of the unities; without staying to inquire how far the French critics have over-rated their importance, it may be generally conceded to the French, that the structure of their plays preserves a compactness and symmetry superior to that of any other stage, and more entitled in that respect to the appellation of clas-

* The horrid piece of Oedipus cannot be fairly pleaded against Voltaire in this respect, as it was written so early in his dramatic career...

Drama.

But classical simplicity reaches no farther in their national drama, than to the mere arrangement of scenes. Their language, their characters, their manners, (we may, without partiality, except some exquisite touches of nature in Racine,) have an exceedingly forced and artificial air. Their eloquence is rhetorical and declamatory. Their passions evaporate in description; and the limitation of poetic language to a certain range of expressions, out of which the sustained style cannot wander, gives a monotony still further increased by the incessant clank of its rhyme. We cannot, however, but repeat, with deference to the name of Racine, that, under all the disadvantages with which he laboured, love speaks in his pages with a sweetness and grace that is always enchanting.

It would be injustice to the genius of France to leave unnoticed the pre-eminence of her comic muse. Three nations of modern Europe may dispute the palm of comedy,—Spain for comedies of intrigue, France and England for those of character. Frequently, perhaps generally, all French and English comedies have a full mixture both of intrigue and portraiture of character; but in that of Spain, the former evidently prevails, whereas, when we come to ask in what consists the exquisite proof of Shakespeare's or Molière's comic powers, we should say, that it is not in contriving a plot, but in displaying the picture of a Falstaff or of a Tartuffe.

The love of comparison may induce us to ask, whether our great compatriot Shakespeare, or the Frenchman, has best succeeded in the portraiture of comic character? This question we presume to suggest, not to solve. The question may be suggested, for it is not a comparison of the portraiture of national manners, but of human nature taken at large. This merit belongs in common both to Shakespeare and Molière. Falstaff is a man comprising the whole world of wit, humour, and laughable vice within himself. The Tartuffe and Avare of Molière, are respectively the consummate portraiture of knavery and avarice, in their most amusing shapes. It is perhaps comparing excellence of different kinds, rather than of different degrees. But the latter, viz. Molière's picture of character, is analogous to what painters would call the hard style; and if humour be the test of comedy, we might with some hesitation pronounce Falstaff to be the more exquisitely comic. The characters of Molière, however, have the undoubted superior merit of being more defined, and less ambiguous than that of Shakespeare's. An essay of no small ingenuity has been written, to prove that Falstaff is really not intended by Shakespeare to be held up as a coward; and it is impossible to read that essay without entertaining some doubts upon the subject. But no stretch of human ingenuity could make us sceptical, for a moment, as to the intention of Molière, with respect to his strong comic characters; and, indeed, when we reflect upon the strength of Molière's drawing, we may well pardon the hardness of his likenesses. The vices of Falstaff, on the other hand, are like his fat form, sleek and undetermined. Molière's villains show, as it were, the skeleton and anatomy of comic nature. One material difference between the two authors is, that Shake-}

* As a general position, the superiority of plays of character over those of plot or intrigue may be asserted; at the same time, exquisite invention of intrigue is a gift of genius which should not be underrated; and though we hesitate not to consider the Spanish drama as deficient in character-painting, yet Calderón, the Shakespeare of Spain, gives such a spirituality to his plot, and makes the incidents which excite a breathless expectation, and a gay convulsion of the curiosity in their transition, so much connection with the character of the personages, that we sometimes may fairly admire him as a painter of character, through the medium of incidents. An exquisite instance of Calderon's comic powers, is his El Secreto a Voz, the best comedy of intrigue that ever the world witnessed—a comedy of intrigue, however, in which there is much mixture of character.
kind of drama may be obtained. The subject of Every Man is the summoning of man out of the world by Death, and its moral, that nothing will then avail him but a well-spent life, and the comforts of religion. This subject and moral are opened in a monologue spoken by the messenger, (for that was the name generally given by our ancestors to the prologue on their rude stage.) Then God is represented, who, after some general complaints on the degeneracy of mankind, calls for Death, and orders him to bring before his tribunal Every Man, for so is called the personage who represents the human race. Every Man appears, and receives the summons with all the marks of confusion and terror. When Death is withdrawn, Every Man applies for relief in this distress to Fellowship, Kindred, Goods, or Riches, but they successively renounce and forsake him. In this disconsolate state, he betakes himself to Good-Dedes, who, after upbraiding him with his long neglect of her, introduces him to her sister Knowledge, and she leads him to the holy man Confession, who appoints him penance. This he inflicts upon himself upon the stage, and then withdraws to receive the sacraments of the priest. On his return he begins to wax faint; and after Strength, Beauty, Discretion, and Five Wits, have taken their leave of him, gradually expires on the stage; Good-Dedes still accompanying him to the last. Then an angel descends to sing his requiem, and the Epilogue is spoken by a person called Doctour, who recapitulates the whole, and delivers the moral. From this analysis it may be observed, that Every Man is a grave solemn piece, not without some rude attempts to excite terror and pity, and therefore may not improperly be referred to the class of tragedy. It is remarkable, that in this old simple drama, the fable is conducted upon the strictest model of the Greek tragedy. The action is simply one; the time of action is that of the performance; the scene is never changed, nor the stage ever empty. Every Man, the hero of the piece, after his first appearance, never withdraws, except when he goes out to receive the sacraments, which could not be well exhibited in public; and during his absence, Knowledge descents on the excellence and power of the priesthood, somewhat after the manner of the Greek chorus. And, indeed, except in the circumstance of Every Man's expiring on the stage, the Samson Agonistes of Milton is hardly formed on a severer plan. The other play is entitled Hick Scornor, and bears no distant resemblance to comedy; its chief aim seems to be to exhibit characters and manners, its plot being much less regular than the foregoing. The Prologue is spoken by Pity, represented under the character of an aged pilgrim; he is joined by Contemplation and Perseverance, two holy men, who, after lamenting the degeneracy of the age, declare their resolution of stemming the torrent. Pity is then left upon the stage, and presently found by Freewill, representing a lewd debauchee, who, with his disolute companion Imaginacio, relate their manner of life, and not without humour, describe the stews and other places of base resort; they are presently joined by Hick Scornor, who is drawn as a libertine returned from travel, and agreeably to his name, scoffs at religion. These three are described as extremely vicious; who glory in every act of wickedness. At length two of them quarrel, and Pity endeavours to part the fray; on this, they fall upon him, put him in the stocks, and there leave him. Pity, thus imprisoned, descents in a kind of lyric man-

Drama of England.

Account of the old drama of Every Man.

Drama in the reign of Henry VIII.

In the time of Henry VIII. one or two dramatic pieces had been published under the classical names of tragedies and comedies. Bale applied the name of tragedy to his God's Promise, in 1538; and, in 1540, John Falsgrave republished a Latin comedy, called Acolastus, with an English version; but these appear not to have been intended for popular use: it was not till the religious ferment had subsided, that the public had leisure to attend to dramatic poetry. In the reign of Queen Elizabeth, tragedies and comedies began to appear in form; and could the poets have persevered, the first models were good. Garboine, a regular tragedy, was acted in 1561; and Gascogne, in 1566, exhibited Jocasta, a translation from Euripides, as also the Supposes, a regular comedy, from Ariosto, near thirty years before any of Shakespeare's were printed. The people, however, retained a relish for their old mysteries and moralities, and the popular dramatic pocts seem to have made them their models. From the graver sort of moralities, our tragedy appears to have derived its origin, as our comedy evidently took its rise from the lighter interludes of that kind. As most of these pieces contain an absurd mixture of religion and buffoonery, Bishop Warburton has derived from thence our 'unnatural tragi-comedies.' Indefensible, however, as tragi-comedies are, upon the cultivated and genuine principles of art, they may be barbarous, but are not so well entitled to the epithet of unnatural; and it seems unnecessary to trace back the origin of tragi-comedy to any circumstance, except the primitive rudeness of human taste, to which, at a certain era in all countries, the mixture of the ludicrous and the serious seems to be perfectly congenial.

After tragedy and comedy had got possession of our stage, the moralities still kept their ground. One of them, entitled The New Custom, was printed so late as 1572. At length they assumed the name of masques, and, with some classical improvements, became, in the following reigns, the favourite entertainments of the court. The old mysteries, (says Dr Percy,) which ceased to be acted after the Reformation, appear to have given birth to a third species of stage exhibition, which, though now confounded with tragedy and comedy, were, by our first dramatic writer, considered as quite distinct from them both. These were historical plays, or histories; a species of dramatic writing which resembled the old mysteries, in representing a series of historical events, simply in the order of time in which they happened, without any regard to

* These are frequently exhibited as five distinct personages on the Spanish stage, but our moralist has represented them by one character.
the great unities. These pieces seem to differ from tragedies, just as much as historical poems do from epic, as the Pharsalia does from the Iliad. The popularity and dramatic cast of the series of poems called The Mirror of Magistrates, Dr Percy conceives to have contributed to make dramatic poetry have this historical form. It has been justly remarked by Watson, that the early practice of performing plays in schools and universities, greatly contributed to the improvement of our drama. While the people were amused with Skelton’s Trial of Simony, Bale’s God’s Promises, and Christ’s Descent into Hell, the scholars of the times were composing and acting plays on historical subjects, and in imitation of Plautus and Terence. Hence, ideas of legitimate fable must have been imperceptibly derived to the popular and vernacular drama. In confirmation of this, Mr Malone observes, that the principal dramatic writers, before Shakespeare appeared, were scholars: Greene, Lodge, Peele, Marlowe, Nash, Lily, and Kyd, had all a regular university education. From whatever cause it may have arisen, the dramatic poetry, about this period, certainly assumed a better, though still an exceptionable form. The example which had been furnished by Sackville was quickly followed, and a great number of tragedies and historical plays were produced between the years 1570 and 1590; some of which are still extant, though by far the greater part is lost. At length, about the year 1591, the great luminary of the dramatic world blazed out, who singly besotted a richer theatre to his country, by his own writings, than the three successive luminaries of the Greek drama gave to Greece in the course of an age. The dramatic glory of England was divided, in point of time, between the latter years of Queen Elizabeth’s reign, and the prior of King James’s reign. It was supported (as it will be hardly necessary to remark) by Shakespeare; but one or two of the minor dramatists of the same age, in particular scenes and passages, and even in some particular traits of dramatic merit, were worthy of being his contemporaries. Among these, we may reckon Massinger, who approached to Shakespeare in dignity; Beaumont and Fletcher, who rivalled him in drawing female characters; and Jonson, proverbially celebrated for the depth of his learning, and the efforts of his learned labour. Until the suppression of the stage by the revolutionary Puritans, the drama continued to be cultivated as the most popular species of poetry; and the works of Ford, Marston, Brome, Shirley, Chapman, and Decker, though no piece of entire and first rate excellence can be ascribed to any of these names, nevertheless exhibit passages of powerful eloquence, and of deep though irregular sensibility. The bounds to which this article has been unintentionally extended, will not admit of individually detailing the characters of those writers; but we cannot omit remarking the style of Chapman, though his general dramatic character is not great, as giving a fair idea of that full and heightened style, which he occasionally possesses in a very fascinating degree. In didactic and descriptive passages, he seems the nearest of our old writers to the manner of Shakespeare. The following lines, we hope, will justify the opinion.

Opinion, the scale of good or bad;—in the tragedy of Byron’s Conspiracy:

There is no truth of any good
To be discern’d on earth; and by conversion,

Nought therefore simply bad; but, as the stuff
Prepared for ass’s pictures, is no picture
’Twill not be found, and must be left with the beams
Of his imaginative fancy through it.
In forming ancient kings and conquerors
As he conceives they look’d and were attir’d,
Though they were nothing so: so all things here
Have all their price set down from men’s conceits;
Which make all terms and actions good or bad,
Which are but plaint and well-coloured threads
Put into flegned images of truth.”

Contempt expressed against the absurdity of astrological calculations:

1. I am a nobler substance than the stars;
And shall the baser order rule the better?
Or are they better, since they are the bigger?
I have a will and faculties of choice,
To do, or not to do, and reason why
I do, or not do this: the stars have none.
They know not why they shine more than this taper,
Or how they work, nor what. I’ll change my course,
I’ll piece-meal pull the frame of all my thoughts;
And what are all your capital then,
Your planets all being underneath the earth
At my nativity? what can they do,
Malignant in aspects in bloody houses?"

Henry the Fourth of France blessing the young Dauphin.—from Byron’s tragedy:

"My royal blessing, and the King of Heaven
Make thee an aged and a happy king.
Help, nurse, to put my sword into this hand;
Hold, boy, by this, and with it may thy arm
Cut from thy tree of rule all trait’rous branches
That strive to shadow and eclipse thy glories:
Have thy old father’s anger for thy guide;
Redoubled be his spirit in thy breast,
Who, when this state ran like a turbulent sea
In civil hate, and bloody enmity,
Their wrath and envies, like so many winds,
Seized and burst; and, like the halcyon’s birth,
Be thine to bring a calm upon the shore,
In which the eyes of war may ever sleep."

His soliloquy, delivering the death of a traitor:

"O thou that governs the keen swords of kings,
Direct my arm in this important stroke,
Or hold it, being advanced—the weight of blood,
Ev’n in the basest subject, doth exact
Deep consultation in the highest king:
For in one subject, Double unjust affrights,
Passions and pains, though he be near so poor,
Ask more remorse than the voluptuous spleens
Of all kings in the world deserve respect.
He should be born grey head’d that will bear
The weight of empire. Judgment of the life,
Free state, and regulation of a man,
If it be just and worthy, dwelleth so dark,
That it denies access to sun and moon.
The soul’s eye, sharpened with that sacred light,
Of which the sun himself is but a beam,
Must only give that judgment.”

The reign of Charles is distinguished in his dramatic annals by the name of Otway, who, in the pathos of Otho’s tragedy, is incomparably the master genius of the English stage. No writer has touched the string of domestic distress with so much force and feeling. His language has at once the graces of fancy and the tone of nature. His affecting situations, like those of Esquivali, are drawn from the deepest resources of tragic art; and his fables (excepting those scenes of buffoon-

DRAPESTES, a genus of plants of the class Tetranteria, and order Monogynia. See Botany, p. 132.

DRAWEAK, a custom-house word, denoting the amount of duty repaid, or, in other words, drawn back, on the exportation of particular articles of merchandise. Drawbacks proceed on the principle, that it is politic to avoid burdening our exports with any extra charges, whatever we may do in regard to home consumption. The writers on commerce generally consider them along with bounty; but while the policy of the former is commonly very questionable, there can be no doubt of the expediency of the latter. To allow a drawback, is, in fact, nothing more than to leave the article as we found it; but bounties operate to give a forced direction to the employment of capital. In many articles, our duties of custom or excise are so heavy, as to make the amount of drawback considerable, and to render the grant of it a matter to be accompanied with great precautions. The exporting merchant must make oath of the former payment of the duties in question; and, in the event of fraud, both forfeiture of the goods, and a penalty in addition, are incurred. Fraud, in the case of drawbacks, is apprehended less from misrepresentation at the customhouse, than from attempts to reland clandestinely, for the purpose of sale at home, the very goods, for the exportation of which the drawback had been obtained. The law accordingly enacts the forfeiture of all vessels, carriages, or appurtenances used in the relanding, along with the forfeiture of twice the drawback, by the party concerned in this iniquitous transaction. (x)

D R A W I N G.

D R A W I N G, or Design, is that part of the art of painting which relates to the terminations, contours, boundaries, of objects in whole, and in their parts. In sculpture it extends no further than to the geometrical arrangement of those terminations, according to their real figure and proportion; but in painting there is superadded to this, the consideration of the perspective appearance of this proportionate arrangement of figure, as viewed from one point. This is called drawing, by way of excellence, to distinguish it from all mere geometrical regular delineations, and is undoubtedly the highest and most comprehensive mechanical excellence of the art.

As all the considerations of sculpture are therefore necessarily included in drawing, and make but a part of it, those principles in which the chief excellence of drawing consists, must be considered as equally applicable to sculpture, as far as it goes. The designer must be conversant with those laws of gravity by which alone all bodies are sustained in action or in motion, by the necessary regulation of an equilibrium in their parts. He must likewise dispose and arrange, in true perspective, all his objects in their proper situations, and relative magnitudes, distinguishing the several qualities of surface, whether of trees, of rocks, of buildings, or of draperies, according to the economy and character of the parts peculiar to each. As the human figure combines a greater variety of important considerations than that of any other subject whatever, all the great designers have devoted themselves to the study of it with such peculiar predilection, that the terms correct drawing, a skilful draftsman, and the like, almost exclusively refer to the skilful delineation of the human body. All the different styles of design may be classed under the three following heads:

1. The indiscriminate representation of ordinary and familiar objects, with all the imperfections and peculiarities of the individual model. This is the vulgar idea of the imitation of nature, and in it nothing is required as far as relates to style and character, but skill and accuracy of the eye and hand. This was the department of art which the Dutch school adopted.

2. The selection of nature, or the representation of Select an objects selected from the mass, with some particular view or design.

3. The grand style, (Beau Ideal, Gran' gusto,) which Grand style is the selection and judicious combination of different
The ideal style comprehends propriety of attitude, elegance of contour, choice of expression, play of drapery, in short, every thing that can elevate individual nature, to the most sublime conceptions of the imagination. "It is not easy," says Reynolds, "to define in what this great style consists, nor to describe by words the proper means of acquiring it. But though there neither are nor can be any precise rules for its exercise or acquisition, yet we may truly say, that it will always be obtained in proportion to our attention in observing the works of nature, to our skill in selecting, and our care in digesting, methodising, and comparing our observations. The power of discovering what is deformed in nature, or, in other words, what is particular or uncommon, can be acquired only by experience, and the whole beauty and grandeur of the art consists in trying to get over all singular forms, local customs, peculiarities, and details of every kind.

"All the objects which are exhibited to our view by nature, upon close inspection, will be found to have their blemishes and defects: but it is not every eye that perceives these blemishes; it must be an eye long used to the contemplation and comparison of these forms, and which, by a long habit of observing what any set of objects of the same kind have in common, has acquired the power of discerning what each wants in particular. This long laborious comparison should be the first study of the painter who aims at the highest style. By this means he acquires a just idea of beautiful forms; he corrects nature by herself, her imperfect state by her more perfect, his eye being enabled to distinguish the accidental deficiencies, excrescences, and deformities of things from their general figure; he makes out an abstract idea of their forms more perfect than any one original; and what may seem a paradox, he learns to design naturally, by drawing his figures unlike to any one object. This idea of the perfect state of nature, which the artist calls ideal beauty, is the great leading principle on which works of genius are conducted."

Beauty or perfection then, is that form of bodies arising from a complete harmony in all their parts, corresponding with the generic qualities of their several species, of whatever kind, sex, or age.

Pure simple beauty, or perfection, being equally adapted to all the several animal destinations proper to its species, is equally removed from the several classes of character which so evidently define and manifest their peculiar powers. Mere beauty of form, though always pleasing, (we speak here more particularly of that of the human body,) is incapable of exciting great interest, till it be combined with the expressions of sentiment and mind; then it becomes interesting and fascinating, and particularly when it is in action, and accompanied by the graces, its natural attendants, which, without altering any of its constituent parts, make the soul and sensations of the heart visible in the external figure, and which, still more in the female, by their affecting sensibilities, and happy transitions, produce on the whole, an air and aspect the most amiable, tender, and enchanting. But although the graceful is so eminently distinguishable, and carries with it such peculiar power in female action, yet it is by no means to be understood as confined merely to female action; for as grace is produced from the union and entire conformity between the tender sentiments of the heart, and the corresponding mild and easy actions of the body, every action or movement of a perfect and beautiful body of either sex, may, even of almost any species where this union is visible, must be graceful. Hence arise that grace, elegance, and dignity of attitude and gesture which we so much admire in the Greek statues; not that these qualities consist in any particular lines of beauty, or depend on the impressions which any specific forms make on the organs of sight, but on the contrary they arise wholly from mental sympathies and associations; and therefore the forms which appear graceful, elegant or dignified in a man, are totally different from those which appear so in a lion, a horse, or a dog, though all of these frequently display grace and elegance of form and motion in a high and eminent degree. There are certain postures into which the body naturally throws itself, and certain gestures which it naturally displays, when under the influence of particular passions and dispositions of mind, so that from our own internal feelings and sentiments, we learn to associate the ideas and notions of certain tempers and characters of mind with those of corresponding attitudes and modes of carriage of the body, as we do more immediately and unconsciously from the features of the face. Upon this principle, dignity of attitude is that disposition of the limbs and person, which, from habitual observation, we have learned to consider as expressive of a dignified and elevated mind, while grace and elegance of form are those dispositions and combinations of motion or attitude, which, upon the same principle, seem to express refinement of intellect, polish of manners, and pleasantness of temper; for though we apply the words grace and elegance to inanimate objects, it is always by metaphor and analogy, as we speak of lightness and heaviness of form, although we know that gravitation has no connection with form, but depends entirely on substance.

In the fine age of the arts in Greece, civilization had just arrived at that state in which the manners of men are polished, but natural, and consequently their attitudes and gestures expressive and emphatical, without being coarse or violent; all the more noble and amiable sentiments of the mind were indicated by the correspondent expressions of the countenance and body; their modes of dress, too, having been adapted to display to advantage the natural motions and gestures of the body, and not to constrain, disguise, and conceal them, like those of modern Europe, the artists had continually before their eyes every possible variety of models. In the pagan festivals, too, where men of high rank and liberal education entered into contests of personal strength and agility, they had opportunities of seeing muscular effort and exertion in every mode and degree. By studying these models, and not by resorting to any abstract rules, or predeterminate lines of beauty or grace, the ancient artists seem to have produced those great masterpieces of art; for, as to particular lines, there are none that may not be graceful, elegant or beautiful, in proper circumstances and situations, and none that are not the reverse, when improperly employed. Accordingly the design of the ancients is distinguished by an union in the proportions, a simplicity of contour, an excellence of character, and a gracefulness of action. If we observe the attitudes and movements of the Greek statues, we cannot fail to mark that careless decency, and unaffected grace, which ever attend the motions and gestures of men unconscious of observation. The ancients could not but derive peculiar advantage from the observation of those living models of elegant and unconstrained nature, which were perpetually before their
eyes. Hence that singular simplicity which characterises their works; for though at times, as in the Venus de Medici, and the daughters of Niobe, they rise to an assumed gracefulness, yet this is confined to so simple a contour, it is so little above the measure of ordinary action, that it appears less the effect of study, than the natural result of a superior character, or an habitual politeness.

We have selected the following statues as specimens of ancient art; each possessing a distinct and well-defined character, in form, proportion, and expression, and may be considered as the head and representative of the class to which it belongs.

Of all the remains of ancient art, there is none that can be compared to the fragment of the Hercules, commonly called the Torso of the Belvedere. In point of sublimity and grandeur of stile, it is unique; it is the most complete system, or combination of parts, that can possibly be conceived, for the idea of corporeal force, which it was intended to convey; the character of all the parts most perfectly corresponds with each other, and with the general idea of the whole. The length and taper form of the thighs are well calculated to obtain the victory in the foot race, which Hercules won at Olympia; but their agility appears more the effect of force than of lightness, and they are in perfect union with the loins, abdomen, chest, and back, which exhibit a power that might well crush Antens. Compared with this, the Hercules Farnese, though possessing much beauty, is heavy and inert. In order to give a more decided character of strength, as is thought by some, the artist has borrowed from the bull the thick- ness of his neck, and the hair of his forehead. The practice of the ancients in giving a character of divinity to their gods and deified heroes, was to suppress the veins and sinews, as is observed in the Torso, Apollo, and others. In the Torso, he is represented as purified from the grosser parts of human nature, and arrived at the felicity of the immortals. The Farnese Hercules is still in the middle of his labours, and man is impressed on the whole figure.

Of all the productions of art, which have escaped the ravages of time, next to the Torso, the Apollo Belvedere is by far the most sublime: his stature is above that of man, and his whole attitude breathes majesty. Here is nothing mortal, nothing that seems subject to the wants of humanity. His body is not heated by veins, nor agitated by nerves, and a celestial spirit is spread over the whole figure. He has overtaken Python, and in his rapid course, has just transfixed him with his mortal weapon.

In the group of the Laocoon, the great aim of the artist has been to impress on the mind of the spectator, those emotions of terror and pity, which arise from that climax of distress, exhibited in the unavailing efforts of an agonised father and his children; the children calling on the father for assistance, and he upon heaven, which has abandoned him to his fate. The forms of the children are full of grace and beauty, and the noble, vigorous, athletic figure of the father, is admirably calculated to exhibit those convulsive writhings which agitate every member. Besides the variety arising from the different ages and characters of the figures, their actions are so diversified, that, in every point of view of this admirable group, the eye is presented with a combination of circumstances and aspects, so beautifully varied from each other, that it is difficult to say which is most to be admired—vital energy, direct, and uniform address of the subject, or the graceful and skilfully variegated manner in which it is communicated.

The Venus de Medici is remarkable for the beautiful expression of her countenance, the elegance and grace of her attitude, and the sweetness and delicacy of her form. This figure has always been considered the model of female perfection, and is a fit representative of the queen of beauty.

The Antinous of the Belvedere, as it is commonly called, has a just claim to be ranked among the finest remains of ancient art; but more for the beauty of the parts, than the perfection of the whole. The lower parts of the body, the legs and feet, are much inferior, both in form and execution, to the rest of the figure; the head is, without controversy, the most beautiful of that class of character now extant. The face of the Apollo Belvedere indicates stateliness and majesty; but that of the Antinous presents the graces of youthful beauty, accompanied with native innocence, without the indication of any passion capable of disturbing the harmony of parts, and the repose of mind, impressed on every feature; his eyes, arch’d with a gentle inflexion, speak a language full of innocence; his cheeks form a fine combination with his elevated and rounded chin, and complete the graceful contour of this noble youth. His chest is powerfully elevated; his shoulders and sides are of a most finished beauty, but his legs are deficient in that fine form, which such a body requires, and his feet are of a coarse and ordinary execution.

The statue known under the name of the Gladiator Borghese, comes next to be considered: The Torso of the herculis, and the Belvedere Apollo, above described, offer the idea in its greatest perfection. The group of the Laocoon presents nature elevated and embellished by the ideal, and by expression; but the merits of this statue consist in the assemblage of the natural beauties of an adult man, without the addition of any thing from the imagination.

The preceding figures are like an epic poem, which, passing from the probable beyond the true, leads to the marvellous; whilst the Gladiator is like history, which candidly exposes the truth, but with the finest choice of thought and expression. The air of his head shews clearest that his form is taken from an individual model; his whole physiognomy presents the idea of perfect manhood, the structure of his members, the traces of a life constantly active, and a body hardened by fatigue.

The arts of design had long been cultivated in Greece, and by the time of Pericles they had arrived at the highest perfection. From that period to the time of Alexander the Great, history presents us with a long and brilliant list of men, whose works in art, as well as letters, have been the admiration of every succeeding age. During this period were produced almost all those stupendous works of ancient art, which have ever since been the standard of legitimate taste, and to which we are solely indebted for all that is great or excellent in modern art since its revival. This was the age of Phidias, Polycletes, Myron, Parrhasius, Zeuxis, and Apelles; and although a general purity of conception is observable in almost all the works of the ancients, even to the lowest class; yet it is to the productions of this time only that the term antique, as a model of perfection, can properly be applied.

Our limits do not permit us minutely to trace the various fluctuations of the arts of design, from this period to their total extinction during the middle ages;
we shall therefore confine ourselves to a very brief epitome of their history.

Under the successors of Alexander the Great, the arts maintained their respectability and consideration till the destruction of Corinth by Lucius Mummius, when the liberty of Greece was buried in its ruins, and all the finest monuments of art were carried to Rome to decorate its triumph. This example was followed by Metellus in Macedonia, after the defeat of Perseus; from this country he took an incredible number of statues, with which he embellished the capital, and the famous portico which bears his name; and Sylla, on the taking of Athens in the war of Mithridates, completed the destruction of Grecian art. The Torso of the Hercules seems to be one of the last masterpieces produced in Greece before the total extinction of its liberty; for after this country was reduced to the form of a Roman province, history makes no mention of any celebrated artist, until the time of the triumvirate at Rome. The bringing to Rome so many fine works of art, seems first to have given to the Romans a taste for the arts of design. These conquerors, when they had relaxed from their severity, began themselves to cultivate the Greek arts as well as letters. The Roman people, sensible of the beauty of the productions of Greece, took pleasure in contemplating them; and that before the art was at all practised at Rome; they even became the protectors of it in its own country, by having statues executed at Athens for their country houses. Before the dictatorship of Sylla, the arts, though esteemed, do not seem to have met with any distinguished success, as during the republic, the Romans affected a simplicity of manners, and the enjoyment of a frugal mediocrity; but as soon as the laws of civil equality began to be subverted by the preponderance of some rich and powerful citizens, who, by luxury and magnificence, endeavoured to awe the people, and to stifle the republican spirit, the taste for the arts began rapidly to increase. Sylla was the first of those who governed Rome as a despot. The destroyer of the arts in Greece, he became their protector in Rome and Italy; he surpassed all in the splendour and sumptuousness of his buildings; Clodius, Lucullus, Lepidus, Pompey, and others, adorned their palaces and gardens with statues; and Caesar, when he conquered the empire, besides erecting superb edifices in Italy, Gaul, Spain, and Greece, made magnificent collections of engraved stones, and of pictures of the ancient masters. Augustus decorated the public places, and even the streets, with statues of the gods, and placed in the portico of his forum those of the most illustrious Romans who had contributed to the glory of their country. The arts of design were now firmly established at Rome, which was filled with artists from Greece, as well as its own natives, who all aspired to honour and emulation under the auspicious influence of imperial patronage. This forms another brilliant epoch of the art. It was now arrived at its climax; but it seems to be the lot of art not to remain long stationary. The train of monsters who immediately succeeded Augustus, brought on a premature decay; and, notwithstanding the countenance and encouragement it received from the Vespasians, Nerius, Trajan, Adrian, and the Antonines, the decline was rapid and uninterrupted; and by the time of Charlemagne, it had sunk to the lowest state of barbarism and degradation, and so continued till the time of Cimabue. Although the renovation of the arts in Rome has generally been attributed to Cimabue, it is certain that they were cultivated for nearly two centuries before him, and, it is supposed, principally by Greeks. The Mosaic pictures at St. Mark's at Venice sufficiently show the low state of the art at this time, being without light and shadow, in miserable drawing and proportion, and the figures standing on the points of their toes. Cimabue began to find out the defects of this manner; and his disciple Giotto, improving on the discoveries of his master, by giving an air to his heads, attitude and motion to his figures, and even attempting the passions and affections of the soul, and more natural folds to his drapery, laid the foundation of that vast fabric of excellence, which, after the gradual improvement of two centuries, and the successive labours of Ghiberti, Brunelleschi, Masaccio, Andrea Mantegna, and their followers, was at last perfected by the genius of Leonardo da Vinci, Michael Angelo Buonarotti, and Raffaelle. Leonardo da Vinci, besides strength and manliness of design, gave all that subtle detail of the exactness of nature; and in the stronger expressions, he seems to have gone farther than any contemporary or succeeding artist, in marking the emotions of the soul in the actions and countenance; and his enthusiasm, though great, is always equalled by the coolness and solidity of his judgment. Although the researches of Leonardo da Vinci were extended to all the parts of painting, his sagacity was so effectual in each, that it may be truly said that the greater part of the excellencies of some of his most distinguished successors was owing, in a great measure, to the discoveries of this scientific and philosophical artist.

Michael Angelo, by the study of anatomy and the antique, had possessed himself of such powers in the naked, as had never been known before him: he formed his taste very much from the Torso, and other ideal statues of antiquity; yet, notwithstanding the vastness and sublimity of his conceptions, his noble enthusiasm, and the correctness and greatness of his style, his works are chargeable with a great want of variety of character, as that of the Torso is too prevalent in them all. His character, however, as a designer, has always been esteemed, as design itself was cultivated and understood; and if his reputation has diminished in latter times, it is because this part of the art has been less attended to, than those that are more showy and superficial. No man has delineated, with more skill, those actions that require spirit and energy; and none, since the revival of the art, has ever equaled him in elevation of sentiment, unity of idea, and consummate knowledge of the figure. See Buonarotti and Raffaelle.

Raffaelle's design was, in its beginning, like that of his master, Pietro Perugino, dry, but correct; he enlarged it much on seeing the drawings of Michael Angelo, though, in his smaller works, he never entirely got the better of that dryness of manner. Of too just an eye to give entirely into the excesses of his model, he struck out a middle style, which, however, was not so happily blended, nor so original, as to throw off the influence of the two extremes; hence, in the great, he is too apt to swell into the charged, in the delicate to drop into the little. His design is, notwithstanding, beautiful, though it never arrived at that perfection which we discover in the Greek statues. He is excellent in the characters of apostles, philosophers, and the like; but the figures of his women have none of that elegance which is seen in the Venus de Medici, or the daughters of Niobe; in these, his convex contours have a certain heaviness, which, when he seeks to avoid, he falls into a dryness still less agreeable. His great excellence in design is more a happy union of all its essential parts, than the energy of any one separately
considered. He possessed all those parts of the art in a high and respectable degree, particularly the expressive, which was his most characteristic and predominanting quality: he shews, in his works, a most beautiful and highly interesting chain of well reasoned and happily variegated incidents, a solid, manly judgment, a divine enthusiastic warmth, and an expressive energy, which have set him above all the moderns in this branch of the art.

Raffaello and Michael Angelo have thus carried the art farther than had ever been done before, and they have never been equalled since. If it be inquired, which of these two extraordinary men should hold the first rank, it will be answered, that if it is to be given to him who possessed the greater number of the higher excellencies of the art, it must be Raffaello. But if the sublime, which is the highest excellence that human compositions can attain to, compensate for the absence of every other beauty, and atone for all defects, then Michael Angelo demands the preference.

Titian's style of drawing is not remarkable for any excellency: he had but little selection, and was closely attached to whatever he saw that was not grossly faulty in the models he drew from; his forms, therefore, though well enough rendered, are generally imperfect; he was ideal and scientific in his colouring only.

On the contrary, Correggio, besides the charms of his chiar' oscuro, gave in his drawing more grace, delicacy, and sentiment, than any of his predecessors, though these beauties often degenerate in him to affectation and inaccuracy, particularly in his larger works. In his oil pictures, wherein he could revise and correct, his figures and expressions are better attended to; and the beauty, grace, and interesting sensibility of his female figures, strongly show how far Raffaello was short of him in this class of character. See Correggio.

The taste of design of Parmeggiano is often an improvement both on Michael Angelo and Correggio: he frequently possesses the spirit and intelligence of the one, with the grace, sentiment, and sweetness of the other. His figures have much spirit and energy of action; they are often singularly beautiful, and almost always graceful; the articulations of the joints show great agility and ease; they are of a fine length and beautiful form, and on the whole display great knowledge of the figure. These beauties are, however, often carried to excess, particularly in the extremities, in the movements and actions of his figures, which, though the seat of his greatest excellence, are frequently overpowered by too much spirit.

The Carracci formed a new style, by uniting all the parts of the art which had separately been cultivated by their predecessors, without giving particular attention to any one; and though they have not equalled the grandeur of Michael Angelo, or the expression of Raffaello, the grace and chiar' oscuro of Correggio, the strength and fine distribution of colour of Titian, their works in general combine more excellencies than had ever been brought together before. Agostino's style of design is better selected from nature, more large and noble, than that of Ludovico; and, from the great perfection he has displayed in many of his pictures, it must be regretted that he dedicated so much of his time to engraving.

The style of Annibal is like that of Ludovico, of a noble and enlarged character, and savours little of the poverty of defective individual nature: he improved greatly on his arrival at Rome, on seeing the great works of Michael Angelo and Raffaello, and above all of the antique, which opened to him new treasures of ideal beauty, of which before he had but a faint conception. The Farnese gallery clearly displays this advantageous change of style; and there is every reason to think, that his great talents, now transplanted to a more genial soil, would have appeared in still greater splendour, had not his career been terminated by a premature death. The vigour which Raffaello and Michael Angelo disseminated over the Roman school, (which was indeed very transitory), would have perished with their immediate disciples, had it not been for the Carracci and their followers, who for some time kept up the credit of sound design, against the meretricious practices of low imitation, and the trite, flimsy, and vague invention of the scholars of Carravaggio and D'Arpino.

The highest rank among the disciples of the Carracci must be given to Guido and Dominichino. The great aim of the former was sweetness, beauty, and divine grace in the airs of his heads, and the attitudes of his figures. He is ranked with the greatest artists of any age since the revival of the art. His style was peculiar to himself; the tender, the pathetic, the devout, in which he could display the sweetness and delicacy of his thoughts, were the subjects in which he excelled. In expressing the different parts of the body, he had a remarkable peculiarity of manner: he usually designed the eyes of his figures large, the nostrils somewhat close, the mouth small, the toes rather too closely joined, and without any great variety; the heads of his figures are accounted not inferior to Raffaello, either for correctness of design or engaging propriety of expression. His most distinguishing talent lies in that moving and persuasive beauty, which proceeds not so much from a regularity of feature, as from a lovely air he has of nothing, which he had the art to place in the eye; and in these qualities he has never been surpassed. Dominichino has been distinguished for fine character, strong and moving expression, sound drawing, and simplicity and variety in the airs of his heads. In these respects he is little inferior to Raffaello; his attitudes, however, are but moderate, his draperies are stiffly cast, and his pencil heavy. The design of Nicolo Poussin is simple, pure, and correct; he lived and conversed so long with the antique, that his works throw us back entirely to those times, and have more the appearance of ancient paintings than those of any of the moderns. His best works have a remarkable dryness of manner, which, though by no means to be recommended for imitation, seems perfectly to correspond with that ancient simplicity which characterises his style. With the severe and rigid manner of Poussin may be contrasted the florid and gay style of Rubens. Notwithstanding the amazing splendour of colouring, the magnificence of his composition, and the ease and dexterity of his execution; his drawing is coarse and vulgar, without dignity or character; and, in short, nothing can be farther removed from the true principles of legitimate art, and the purity and chasteness of the antique, than the general style of his design. His manner was followed by a numerous train of disciples, at the head of whom is Vandyke, who possessed all Rubens' excellence, with more grace and correctness.

The Dutch school has never directed its aim to any thing but imitation of individual nature; but, as far as that goes in the representation of drolls, conversations, landscapes, and sea pieces, and in seizing those transitory effects of light and sunshine, in beauty of colouring and chiar oscuro, and in the mechanical dexte-
rity of the pencil, the art has been carried to the highest point of perfection; and it is to be regretted that many of the painters of this school, in the humble sphere to which they limited themselves, have displayed talents which, if they received a proper bias, would have given them rank and eminence among those who have excelled in the higher departments of the art.

We have taken no notice of the French school; for although several artists of that nation, such as N. Poussin, Le Brun, Sebastian Bourdon, and Le Sueur, hold a high rank in the art; yet as the French taste has always been much more inclined to the frivolities and affectations of Watteau and others, than to the genuine principles of sound art, these must be considered rather as a colony of the Roman school.

Drapery. The judicious choice and disposition of the draperies, form another important subject for the artist's attention, whether considered as contributing to the expression of the character represented by the propriety of costume, or as affording additional assistance in giving grace to his figures; in uniting the parts of a group, or one group to another; or as forming a substratum on which he is to dispose the variety of colour and strength of chiar oscuro, so essential to the pleasing effect of his work. Its excellence consists in three things, viz. 1st, The disposition of the folds; 2d, The diversity of the stuffs; and, 3d, The harmony produced by the scientific arrangement of the colours.

The drapery, in its folds, should be so disposed, that the character of the form, and proportion of the figure, should appear, as far as probability will allow. It was usual for the great masters, first to draw their figures naked, and then to adapt their drapery to their position. Whatever be the motion of the figure, the folds of the drapery should always show distinctly the action and attitude of the figure, and the true position of the body. In the composition of many figures, attention must be paid in the folds to the variety produced by the qualities of thick or thin stuffs, as adapted to the characters of the several figures. In the representation of philosophers and prophets, in order to correspond with their dignity and gravity of deportment, the folds should be few and large. In men of elevated character, and matrons of a superior class, such as the Virgin Mary, and the disciples, the folds will not be so few nor heavy as in the former; and for nymphs or young females, the drapery will be light and thin, and the folds small and numerous. Regard also must be paid to the rank and condition of the several characters, in the introduction of suitable ornaments, such as jewels, embroidery, rich robes for queens, princes, &c. The introduction of diversity of stuffs, does not seem consistent with the dignity of historical composition, which is always degraded by individual representation. On this principle, the Roman, Florentine, and Bolognese schools, have never given greater variety to their stuffs than what was necessary for the difference of size in the folds. The Venetian school, on the contrary, which sacrificed every thing to the richness and splendour of effect, have taken the most unbounded license, even in those subjects where the most rigid severity of style would have been most appropriate, in the profuse introduction of silks, satins, brocade, and embroidery, which are only to be admitted in those conversations, and other subjects of individual life, in which the Flemish and Dutch schools have so pre-eminently excelled.

Drapery is also of essential service to the painter in the harmonious distribution of colour and chiar oscuro, and in stamping the character of solemnity or gaiety suitable to the subject; but we shall not enter on the further discussion of this subject, as it belongs to the two great parts of the art—colouring and chiar oscuro.

See Painting.

Raffaello, in his first works, imitated his master Pietro Perugino, in his drapery, as well as in every thing else. He somewhat improved his style from the works of Massaccio and Fra Bartolomeo di S. Marco. On seeing the works of the ancients, he abandoned altogether the schools of those masters, and adopting such rules as he formed from the study of the antique, for the natural folds of his drapery, he acquired that admirable taste by which his folds are distinguished, and in which he has never been equalled.

Correggio, in his drapery, kept always in view what was agreeable or pleasing. He very early quitted the manner of his predecessors in art; he, in general, painted his figures from small models, which he clothed with pieces of cloth or paper. He sought every where for masses, and in those masses for what was pleasing, in preference to the truth of individual folds.

Titian painted his draperies, as he did most other things, merely from imitation. He made them very beautiful, and strongly resembling nature, but exactly as he found them in the object before him, without choice in the folds.

The critical knowledge and just theory of the art, which are to be matured by the study of the antique and the works of the great masters of the Italian schools, must be founded on an intimate knowledge of the human figure, in its various states of action and repose, of the effect of the passions on the face and body, and its symmetry or proportions in its adaptations to the various characters of youth, manhood, or age; strength, agility, or delicacy, of plumpness or leanness; for the several degrees of which, in every possible combination, have each of them a conformity of parts, and a proportionate arrangement of relative magnitudes peculiar to itself; and this knowledge of proportion is only to be acquired by the accurate investigation of general nature in its approaches to the abstract of each character; and the more we are practised in this study, the better will we be enabled to appropriate to each character the peculiar proportions which constitute it. The antique statues are excellent examples of the mode of study to be pursued in adapting proportion to character, by a happy conformity of each to the other; and though they apply but to few characters, as but few remain entire, yet enough is left to point out the way; for the greatest absurdities must follow, when the proportions and form of the muscles are not adapted to the character of the figure; and the degree of muscular exertion to the occasion of calling it forth, as is the case with the works of Lanfranco, Pietro da Cortona, Carlo Cignani, Le Moine, and others, who have indulged so far in this fondness for some particular proportions, that their figures are all of the same family and character, with no difference but what arises from action, position, or age; and this can only be acquired by the study of anatomy, which is the grammar of painting. Without anatomy, the most careful examination of the figure will be of no avail. As the display of muscular action is but necessary to be fixed or retained, the effect produced upon the external surface of the body and limbs by the action of the muscles, the swelling and retiring of the fleshy parts, and the appearances of the sinews or tendons, which accompany all the varieties of exertion or change...
of posture, cannot be perceived with sufficient accuracy, without the knowledge necessary to classify the muscles engaged in the operation, and account for the changes of form superinduced on the surface by the various motions of the bones, particularly at the articulation of the joints in the different actions of flexion and extension; and it is only by a minute comparison of their forms and situations, as they appear on dissection, with the living subject put in every variety of action, that this knowledge can be attained. It was by this practice that the great masters, particularly Leonardo da Vinci, and Michael Angelo, acquired such profound knowledge, and such exquisite correctness of design; and there are still extant many highly finished drawings by them in this way, which abundantly prove with what indefatigable industry and minuteness of investigation they applied to this study.

The human figure, in various stages of existence, from infancy to maturity and old age, undergoes many changes, which, without invading the province of anatomy, we may briefly notice. Infants of both sexes bear a strong resemblance to each other, in form, delicacy of organization, plumpness and gait, and the size of the muscles. But after a few years, when the organs are more fully developed, the muscles of the male lose their original softness and rotundity; become firmer, larger, and of a more determinate figure, till at last the original rotundity entirely disappears; the muscles, particularly in action, are seen distinctly through the skin, and strongly indicate superior strength and activity. The delicate organs of the female never acquire the same bulk, strength, or rigidity, as those of the male: on the contrary, they retain their original softness and delicacy of texture; no rising muscle projects, to break the gentle undulations of the form. The form of the child's head is powerfully distinguished from that of the adult, by certain striking peculiarities; as nature, for wise purposes, brings the brain sooner to perfection than any other organ, its size, and that of its case the skull-cap, (or cranium), is larger in proportion than that of the body, and the face is remarkably small for want of the teeth and gums; but in its progress from infancy to youth, the growth of the teeth deepens both the upper and lower jaws, and to give room for the full set, the jaws are elongated: the bones of the nose are raised, the nose is lengthened, and the cheek bone is made to project, and the frontal sinews are formed, which complete the character of the adult. When the teeth fall out in old age, the alveolar processes which grew up with them, and supported them, are removed by absorption; and there remains nothing but the narrow base of the jaw, while the length of bone from the hinge of the jaw to the angle is undiminished. The jaws, then, are allowed to approach nearer each other at the face part, the angle of the jaw comes more forward, resembling that of the child, and the chin projects also. The teeth and adventitious parts of the jaws being gone, the chin and nose approach, the mouth is too small for the tongue, and the lips fall in. In their ideal figures, the ancients did not confine themselves strictly to the natural form of the head; their practice, by filling up the cavity between the forehead and nose, and thereby uniting them, and also by giving a greater projection to them than is ever to be found in nature, was to include both within one straight line. This deviation from the universal practice of nature, seems to have arisen in a desire to give a more exalted and divine character to their gods, heroes, and the like, by magnifying those proportions which constitute the distinguis

guishing characteristic of the human countenance, in opposition to that of the lower animals; and this will appear more evident on comparing those forms and proportions which distinguish each from the other; though in their busts and portraits of individuals, they seem to have copied correctly the models they had before them.

In viewing the human head in profile, it will be found that a line from the opening of the mouth, (the alveolar process of the jaws), and another from the same point to the projection of the chin, will form an angle so obtuse, as to deviate little from the straight line, owing to the prominence of the forehead and chin; this is called the facial angle; the eyes lie in the cavity formed by the projection of the forehead, the proportion between the face and the cranium is nearly equal, as a line drawn across the eyes divides the head into two equal parts, reckoning from the crown of the head to the base of the chin. In the heads of all the lower animals, on the contrary, the facial angle is very acute, the nose and forehead are flat, and fall back, and the eyes are very prominent; and the face, up to the beginning of the frontal bone at the middle of the orbit of the eye, (which forms the boundary between the face and cranium), will be found much larger, commonly two-thirds, than the space from this point to the crown of the head; and the fullness and protuberance of the chin, which forms so beautiful and striking a characteristic of the human countenance, entirely disappears, leaving nothing but an uninterrupted straight line from the gums to the angle of the jaws. This subject will be found more amply discussed in Professor Camper's treatise on the connection between the science of Anatomy and the arts of Drawing and Painting, from which the student will derive much useful information.

Besides the anatomy of the human body, which is so sure a guide in drawing the figure, the artist, who aims at truth in the representation of animals, will do well to pay some attention to the study of comparative anatomy, more particularly the mythology and osteology of such animals, domestic or otherwise, as occur most frequently to the painter in the exercise of his art. Notwithstanding the variety in the structure and organization of the lower animals, as adapted to the habits and modes of life peculiar to each, the analogy between these and man, (we speak more particularly of quadrupeds and birds,) is so great, that the knowledge of the anatomy of the human body will form a sure foundation for this other part of the science. Although the Dutch school has produced many artists eminent as painters of animals, such as Du Jardin, Berghem, Van de Velde, Bamboccio, Cuyp, Wovermans, and others, yet none of them seems to have studied with such minute attention the anatomy of animals as Paul Potter; these he has drawn with great truth, spirit, and intelligence; he sometimes, however, makes so ostentatious a display of his knowledge of the bones, as to give a character of leanness and poverty to his animals, ill suited to the richness and beauty of his landscape. Cuyp's great aim was rather a good general arrangement of his figures, as subservient to some brilliant effect of sunshine which he had in view, than any particular minuteness of details; accordingly his animals particularly have much colour, and well grouped, display none of that scientific drawing, which is so desirable, and which we admire so much in the works of Paul Potter, Du Jardin, and some others of that school.

Stubb's great work on the anatomy of the horse will afford the best assistance to the student in the investi-
The ancients, according to Vitruvius, divided the human body into eight heads, or ten faces. The face is reckoned from the top of the forehead at the root of the hairs, to the bottom of the chin; the head from the crown to the same place. In a well-proportioned man, whose arms are stretched out, the distance between the extremities of the fingers of the right and left hands, should be equal to his height, his figure therefore may be included in a square. The proportion of the female figure was formed about one face shorter than that of the male; but it differs from the male more in form than stature. The shoulders are narrower, more rounded and softened than in the male; the chest is more convex, the breasts more elevated, the abdomen more prominent, the loins longer, and the limbs proportionally shorter; the pelvis is broader, and consequently the thigh bones more distant from each other, and inclining inwards with a rapid slope as they descend. The feet and hands smaller, dimpled, and more delicately turned; and on the whole, the abrupt turnings and projections of the muscles, which, in the male, are the mark of his superior strength and energy, are, in the female, rounded and smoothed into lines of the utmost grace and delicacy.

We have extracted from the work called *I Princìpi del Disegno*, published at Rome by Volpato and Morgagni, the following measurements of the three principal statues of antiquity, which, for the sake of more easy comparison, we have reduced to a tabular form: they will give a more perfect idea of the proportions adopted by the ancients, and the distinctions between the male and female characters. In order to preserve uniformity in the measurements, the head of each figure is divided into twelve parts, and each part into six minutes.

</table>
The theoretical parts of the art, which are equally applicable to all the branches of it, as far as they respectively go, from sublime allegory to the humble departments of flowers and butterflies, will be found, in what relates to the form of objects, in the preceding article; and the great principles of chiaroscuro and colouring, will be more clearly elucidated under the article Painting: We shall here, therefore, consider drawing only in a practical point of view, by treating of the processes and operations employed in the various parts of it.

As the principal and most distinguishing attributes of most objects are contained in their form, the foundation of every branch of this part of the art is correctness of outline, without which the finest colouring and most laborious finishing will fail to convey the true character of the object to be represented.

In copying any object, or set of objects, whether from nature or from a picture, it is evident that, on whatever scale it is performed, whether larger or smaller than the original, the proportion of the parts to the whole, and of one object to another, in the various relations of length, breadth, height, and distance, is the basis of correctness of form and true delineation.

Whatever department of the art may be the student's ultimate aim, the habits of correctness, and accuracy of eye and hand, which are desirable in all of them, will be best acquired by careful practice in drawing the human figure, whether from prints, drawings, or from plaster casts. As the gentle undulations and delicate inflexions of form, of which the human figure is in a most peculiar manner composed, demand the utmost attention, and as the slightest inaccuracy instantly discovers itself, by distorting, or at least changing, the character of the object, his eye will speedily acquire that facility of minute discrimination, which will extend itself to every species of objects, and render every thing easy which he may afterwards attempt, whether animals, the ramification or foliage of trees, buildings, mountains, &c.

Although it is usually recommended that the student begin with detached parts of the human figure, such as eyes, noses, hands, feet, and the like, and that when he has acquired tolerable facility in this, he may proceed to whole figures, yet he will derive greater advantage from beginning these at once. The figure ought of course to be simplified in its details as much as possible, and, that it may be the more easily comprehended, a certain formality in the attitude may at first be advisable, which may afterwards be gradually varied, according to the progress of the student. He will thus acquire sufficient accuracy in the smaller parts; and, what is more difficult, a correctness and facility in arranging and disposing the larger masses of the several members, according to their various proportions and relations to each other.

In beginning an outline, the general proportions of the larger parts should be first blocked out, if we may use the expression; and these may be considered rather as to their situation than their form. When this has been done with sufficient accuracy, he will then gradually descend to the more minute parts, till the whole is completed. The advantage of this method is sufficiently obvious; for if the student begin with the more minute parts at once, finishing his outline as he goes on, he will not proceed with the same certainty; the parts will not be so well put together; and when a correction is to be made in the general inclination of an arm, a leg, or the trunk, all the time and attention that he has bestowed on the minutiae are entirely thrown away.

In marking out the leading lines and points of the object to be copied, he should begin by assuming the size of some part of the figure; the head, for instance, to which all the other parts are to be proportioned, according to their relative magnitudes, whether larger or smaller; and a few of the most prominent points should be carefully marked in their true proportions, according to their respective distances and bearings, whether lying horizontally, obliquely, or perpendicularly with each other.

In order to assist the eye in placing the various parts in their proper, relative, perpendicular situations, a small plummet is sometimes used; but it is better to habituate the eye to lead itself from one point to another in any given direction, without any other auxiliary than the correctness which careful practice may have given it.

With regard to the style in which the lines ought to be executed, the student ought to aim at something further than a correct, neat, and distinct outline, such as may be best suited to the form and surface of the original; as freedom and boldness of execution, which dazzle and mislead the ignorant, are qualities which practice only can give, and, when sought after, are too apt to lead to the greatest of all defects, affectation and manner.

It has often been recommended to beginners, and that by respectable authority, in order to enable them to turn their hand, to practise the drawing of straight, curved, and parallel lines, without reference to the delineation of any particular object; but all this may be as easily acquired at the same time that the learner is improving the correctness of his eye, by the representation of objects wherein every species of lines occur; and no one is better calculated for this purpose than the human figure.

When the student has attained considerable proficiency in outline, he may proceed to the shading of his figures, which may be done with black lead, black or red chalk, or Indian ink, bistre, sepia, or the like. But black chalk is, upon the whole, best adapted to this purpose. There are several ways of using the black chalk, viz. by the method called hatching, which is performed by parallel lines crossing each other at certain angles, according to the nature of the shadow and form of the object represented, which is the same principle as that on which stroke engravings are executed: as also by smooth shadows produced by the chalk, without the appearance of any lines. Of this last there are many varieties, which we shall presently notice. The first mentioned of these methods, which, when skilfully executed, has indeed a very good effect, is not to be recommended to the painter, as the laying the lines, as the engravers call it, is so difficult and so essential a part of this mode of working, that the student is apt, in attending to this subordinate part, this language in which he is expressing himself, to neglect the subject of which he is treating. To the young engraver, it may, however, be useful in assisting him in the practice of the mechanism of his art.
The outline being carefully made out in black chalk, a little of the scrapings of the chalk should be rubbed over all the shadows with a stump; an instrument made of chamois leather, rolled up tightly in a cylindrical form, and cut at both ends to a point. This performs the operation with great smoothness, and makes an excellent ground for the finishing, which is done by working up the shades to the requisite depth with the point of the chalk.

The lights must be put on with white chalk, and blended carefully into the middle tint, (the colour of the paper,) by a stump kept for the purpose; and the greatest care must be taken to keep the black and white chalk from coming into contact, as their meeting will produce a disagreeable and unharmonious colour.

In drawing on white paper, the outline should be made out with the chalk, and the shadows rubbed in with a stump, and wrought up to the proper depth, as already mentioned, till the shadow be sufficiently smooth. Any errors in either the outline or finishing may be corrected by rubbing them out with the crumb of a new loaf, squeezed together into a convenient shape. This method is much more tedious and difficult than when it is performed on tinted paper, as it requires infinite labour to give sufficient smoothness and delicacy to the surface. Sometimes a middle tint is formed by the scrapings of chalk laid on with the stump over the whole paper, and the lights taken out entirely with the bread. This method, when well executed, has a beautiful effect; but the time and practice necessary to do it well, render it totally unfit for an unexperienced hand.

In drawing in Indian ink, the outline should be made out with black lead, which in this case is preferable to chalk. The great masses of shadow must be laid in first, and, beginning with the tints much lighter than is wanted, smoothing them in with a wet hair pencil, and repeating the process till the shades be brought up to their proper depth; taking care that each shade be perfectly dry before another is put over it.

For slighter sketches, where boldness and freedom of outline are principally aimed at, as in studies for the composition of larger works, a pen was much employed for the outline by the old masters, particularly by those of the Italian schools, and slightly shaded with the hair pencil, with bistre, sepia, or the like. The drawings in this way of Leonardo da Vinci, M. Angelo, Raffaello, the Carracci, Parmeggiano, and others, are deservedly much esteemed, and frequently sell at very high prices. Of all these methods which we have mentioned, that which we would particularly recommend, as combining utility and expedition, is that of the black and white chalk upon tinted paper. The tint of the paper should be light, that the black chalk may be seen distinctly upon it, and, in order to avoid the coldness and harshness which paper of a dark shade always gives to light put in with white chalk, or any similar substance. In making any correction, a piece of new bread is preferable to Indian rubber; and if any greasiness appear by the too frequent use of the bread, so as to prevent the paper from receiving the chalk readily, warming the paper at the fire will in a great measure remove it.

The student should at first occupy himself for some time in copying from drawings only, and when he has acquired, in some degree, the management of his materials, and a knowledge of the method of expressing himself, he will do well to begin to draw from good casts from the antique, and after that to go to nature; but in this stage of his progress, he will go little way without the assistance of anatomy, the use and necessity of which we have already most anxiously inculcated in the preceding article.

In the management of light and shadow, whether as applied to the human figure, or to any other subject, there is perhaps no one circumstance so conducive both to truth and beauty of representation, as "breadth of effect." In the language of art, breadth is opposed to what is called spotness. Breadth implies, that the lights and shades be arranged in large and broad masses. The separation of the lights and shades into many small parts, leads to the unpleasing effect of spotness. Both of these appearances are often exhibited in nature. But in every instance, the one is delightful, the other is tending to the sense; the former is essential to beauty and grandeur, the latter, unavoidably, is productive of littleness. Its great principles will be more fully treated of under the head Chiari occulto, (see Paintiko;) but we shall, in a summary way, take notice here of as much as is connected with the drawing of single figures.

In looking at a statue or plaster cast, with the light coming on it from one point, the delicate and almost imperceptible transition from light to dark are very obvious; every feature has the most complete relief, even on the parts where the shadow is most delicate, as well as on the dark side of the figure, while the shadows on the different parts of the dark side are sufficiently distinct without harshness; and throughout the whole, nothing obstructs itself to the eye to interrupt the general roundness and repose, or, as it is called in technical language, to cut it up. These delicate interlaced and gradations of shadow, on the light parts of the face and body, which in reality are little removed from the brightness or clear light, being so well defined in the model, are apt to be mistaken by the inexperienced student, and to be made so dark as to leave him no power of giving, with his chalk, the necessary depth of shadow, and consequently roundness to the whole; he must therefore attentively consider the effect of contrast, and endeavour to distinguish what is in itself light or dark, from what may appear so from its being placed near to tints of an opposite character: in this he will derive much assistance from looking frequently at his model with his eyes half shut, or through a Claude Lorraine glass, (a lens of a very dark colour,) or even a piece of window-glass, blackened with the smoke of a candle, as he will by this means lose sight of the particular forms of the more minute parts, and he will see only the great masses of light and shade, and thus be more accurately discriminate between what is light, middle tint, or pure shadow, the right management of which constitutes so great a source of beauty in the human figure, which, from the rotundity of its form, displays so fine an illustration of this principle. The judicious introduction of the reflected light, affords the greatest assistance in giving accuracy and distinctness to the details of those parts of the figure which are in shade, and likewise in giving the requisite roundness and delicacy. These reflections are always to be seen in nature to a certain extent; but when they do not appear with sufficient strength, they may be assisted by setting up a sheet of white paper, or the like, at such a height and distance from the model as may be best suited to the effect required.

In drawing from nature, or from the plaster cast, the model should in general be placed, with regard to the light, in such a situation, that at least two-thirds of the figure be illuminated; and when the light comes in from above, it has a still better effect; but this position of the
figure will be of course modified, according to the taste of the artist, or the intention he may have in view. In order to have a good view of the figure, it should never be nearer the eye than twice its own length. Those general precepts which we have given above for drawing the figure, apply to a certain extent to all visible objects, varying and modifying the style of outline and shading in the way that seems best calculated to express the qualities of form and surface of objects he is imitating; and this talent will be best acquired, by the attentive observation and comparison of nature with the works of other artists.

In the drawing of landscape, the same process in the outline must be adopted as in the figure or other objects; that is to say, to begin with those great lines which bound the principal masses, and from these to proceed to the smaller ones; but as the various objects which it is the province of landscape painting to represent, differ most essentially from the human figure, and from each other, a separate style of outline must be adopted for each. A tree, for instance, as it consists of many small parts, which it is impossible for any mere outline to represent, and as these parts vary considerably in their appearance, according to their distance and their condition with regard to light and shade, such a mode of imitation must be adopted as will best express, in a general way, those appearances; whilst, in those near the spectator, even the character, both of the foliage and ramifications of the species to which it belongs, whether oak, ash, beech, &c. must be attended to.

As the forms of hills are distinct and well defined, they do not admit of that latitude of generalization which must necessarily be allowed in the drawing of trees; every feature must be marked distinctly, and with almost the same accuracy, that we have inculcated in drawing the figure. Lines, besides what is sufficient to express the exact contour of the object, should likewise be touched here and there over the whole object, when near enough to be seen distinctly, in order to convey a true idea of its acclivity and of its surface, whether broken by precipices, or covered with wood, and even expressing the character and position of the strata of which it may be composed, when visible. The necessity of this cannot be too much pressed, as it is too frequently the practice, by neglecting it, to give a form and character so different from the original, as to render it hardly recognizable.

In drawing architecture, (we speak here not of geometrical elevations and plans, but of architecture as forming a part of landscape painting,) when the surface is smooth, the outline must be executed with a clean straight line, and a ruler may even be occasionally employed to advantage; great attention should be paid to the squaring and precision of the turnings in the corners, doors, windows, &c.; and on the parts where the shadow comes, the objects may be marked with a firm dark outline.

In drawing any set of objects, which are all of the same size and height, such as a range of windows, arches, or columns, in order to keep them in their proper places, lines should be drawn as light as possible, according to their perspective inclination, which will include the upper and lower part of them all; and before making them out individually, these lines must be divided, according to the number and situation of the objects, whatever they may be. By this means, the position and magnitude of each will be accurately found; much trouble in altering and correcting will thus be saved; and the occult lines will be rubbed out as soon as the delineation of the several objects is completed.

Without a knowledge of the rules of linear perspective, nothing in this way can be well done, as nothing in painting occurs which is not subject to the influence of its laws; as the beauty and truth of such objects, besides the spirit and character of the outline, depend much on the proper inclination of the lines of the various objects, according to their convergence to their respective vanishing points; and although much careful practice may give a general correctness of perception to the eye, which may prevent gross mistakes, yet as the principles are wanting which give certainty and decision, perpetual errors will intrude themselves; and to the more intelligent critic, the artist's ignorance of this indispensable requisite of his art will instantly display itself.

We shall now proceed to give a few hints on some of the more minute parts of the practice of outlining. These, to some, may perhaps appear trifling and impertinent; but as method is most essential in every mechanical art, and mere delineation is nothing else, we are convinced that the student will readily assent to their utility; for, though, by experience and practice, he will ultimately find them out himself, yet as they are not so obvious at first, his progress will be much accelerated by their communication.

In drawing arches, or other similar objects, whether of a circular or elliptical form, the vertical lines on which they rest, representing their piers, should first be drawn; the points from which they spring at both sides, and the highest point at the key-stone, should then be marked; and before these points are connected by their proper lines, he will be able to form an idea of the appearance and proportion of the part; and he will proceed with his work with less doubt and uncertainty; he will likewise attend to the radiated appearance of the joints of the stones that compose the arch, taking care that they converge to the centre of the circle of which it is formed: this ought to be particularly attended to; and, by neglect of this rule, younger students are apt to betray themselves in drawing objects of this sort. When any line, whether straight or curve, lies in an oblique direction, in order to assist his eye in judging of the angle of its inclination, he ought to mark points for both ends of that line before drawing it; and in objects wherein an approximation to the figure of an isosceles triangle occurs, as in the gable of a house or the pediment of a portico, in order to preserve the necessary uniformity of the sides, he must scrupulously attend to the situation of the apex of the angle, considered both with regard to its height, and its relation to the perpendicular lines, at both ends, on which it rests. In delineating ruins, the lines must be executed in a more ragged and uneven style, than in buildings of a smoother character; making out carefully the forms of the several parts, and giving that precision and firmness in all their details, which instantly convince the spectator of the intelligence of the draftsman, and the truth and accuracy of his work.

In making an outline, the mode of practice adopted by many, is to divide the edges of the drawing to be copied, into any number of equal parts, like the degrees of latitude and longitude in a map. The points at the base of the drawing will give the situation of the perpendicular lines, and those on the sides their heights, and vice versa, the places of the horizontal lines will be found by the points in the sides, and their lengths by those on the base; but as this method is not appli-
Cable to any extent to drawing from nature, to which every practical device ought to have a reference, it is only to be recommended to the beginner, who at first may find some advantage from it.

In drawing from nature, it is necessary to begin by fixing the boundaries of each side, which, in general, ought not to extend farther than what can be conveniently seen at one view, without turning the head, subtending an angle of about 60 degrees. He will thus be able to regulate the proportion and quantity of the subject he means to introduce, according to the size of his paper; by dividing between those boundaries, and observing what lines or objects coincide with those points and their subdivisions, he will easily find their places and relative distances; and the heights of the several objects will be found, by proportioning them to their breadth, or by regulating them by the situation of any other object which may be on the same level; for this purpose it will be found of great service to fix, as soon as possible, the height of some long horizontal line, the horizon itself, when it occurs, and to adapt the height of the several objects, whether above or below this line, according to the distance of the point required from it, compared with its own breadth, or that of any other object already marked. When the places of the several parts are thus found, for their forms in this first stage of the process are entirely out of the question, the details may be entered into, always giving the preference to the larger parts, and keeping in view what has been already said about the methods to be adopted in making out the various minutiae.

There is no part of landscape painting more neglected in general practice, and none where the artist has a better opportunity of displaying his taste and correctness, than in representing the beauty and variety which nature exhibits in the foliage of trees. This will be apparent, if we consider the works of Claude Lorrain, whether in his pictures or etchings, or even in the fine engravings after him by Vivares and others, we will mark that grace, beauty, and truth, which are no where else to be found, and which place him in this respect above all praise, and sufficiently show what may be done by the careful imitation of nature, guided by sound judgment and good taste; while the great inferiority in this point, from whatever cause it may have arisen, of his pupil Swanevelt, and many of the most eminent landscape painters, sufficiently shows both the difficulty and high importance of this part of the art.

The study of architecture, which, in itself considered, is of the greatest importance to the landscape painter, from the high tone and elevated character which its judicious introduction gives to his works, is likewise a useful auxiliary, in enabling him to give precision and character to the angles and turnings of his buildings, which, even to the mere woman of views, and the younger practitioner, are qualities of some consideration, and well worth the trouble of acquiring.

When the student has attained a sufficient accuracy of eye and facility of outline, he may proceed to the shading of his drawings, either with black lead or black chalk. As those delicate transitions and modulations of light and shadow, which are so necessary to the correct representation of the human figure, do not occur in landscapes, he may perform this operation with more boldness and freedom. Instead of that scrupulous attention to the smoothness of his surface, by blending into one tender and even tint the touches by which his shadows are produced, the lines may be kept separate or not, according to the depth of shadow or effect which the quality of surface may require. Particular rules for executing the lines will not be of much use, as copying good drawings, and observing the manner practised by the old masters in their etchings, will afford more instruction in this point than all that can be said on the subject. In general, it may be said, that the lines which compose the shadows should lie in the direction of the object itself, that is to say, that in a perpendicular wall, or similar object, the lines should be perpendicular; in an inclined object, the lines should incline; in cylindrical or spherical objects, a tower, a column, or a ball, they should take a curve direction. Perpendicular objects may also be shaded with horizontal lines, and that either wholly, or, for the sake of greater richness of effect, alternately with perpendicular ones. When the sides of an object are so situated with respect to the point of sight, that, instead of being horizontal, they converge to their several vanishing points, the lines of the shading will follow the same direction as the objects themselves. In shading buildings, or indeed any object wherein accuracy and precision are so essential, of whatever scale it may be, no more of a shade should be attempted than can be conveniently done by the motion of the fingers and thumb, while the hand rests steadily on the paper; and the joinings of those parts, which must be done with a careful freedom, if we may use the expression, will give a certain degree of richness and variety to the appearance, which could not be so well expressed in any other way; but in such objects as have not a form so well defined, particularly when they are large, and require a smooth and flat tint, such as the sky, hills, &c. the shades may be done by the motion of the hand or the wrist, keeping the arm steady, and with an oblique line, which is most convenient for this position of the hand. Plate CXXXVI. will illustrate further what has been said in this branch of the practice of drawing.

Fig. 1. represents the gable of a house, so placed with regard to the spectator, (that is parallel to the ground line,) as not to be affected in its form by its perspective situation. The vertical lines a, b, are first drawn, and the points at a and b, whereon the roof is to be placed, which are both of the same height, are marked in their proper places, in order to give the two sides of the roof the same degree of inclination. The space between a and b is divided into two equal parts, which gives the point over which the apex of the angle is to be placed.

Fig. 2. is the same object, seen in perspective. The points a and b, instead of being of the same height as in the other figure, converge to a vanishing point, so that the two portions of the occult line a, b, from a to c, and from b to c, though in themselves equal to each other, are now by their perspective situation considerably changed, both in their relative height and distance from each other. The point b is lower than a, and the space between b and c being further off, and consequently seen under a smaller angle, is smaller than that from a to c. The perspective centre c will be found by producing the vertical lines a and b to any height, as at e, from which point a vertical line will be drawn to the vanishing point f. The intersection of the line ef, at the point g, will give the line eg of the same perspective length, and parallel to ab, which will represent two sides of an oblong square; the vertical lines ae and bg will give the remaining two. In order to find the centre of the line ab, over which the apex of the angle of the roof is to be placed, diagonal lines ga, and gb are to be drawn, the intersection of which will give the point h, through which the vertical line lc will be drawn, which divdes the line...
a b into two equal parts c, as required. On the line
P on whatever height, at a, k or l, the place of the
corner of the pediment will be marked, and the lines i a,
i b, k a, b or a, b, l, will be drawn according to the height
required.

Fig. 18. is an example of the method of shading objects,
the surfaces of which are not so regular, the sky, trees,
hills, &c. The lines are here zig-zag, their distances are
kept equal, and they may be crossed to increase the
depth of the shadows.

The student will derive much advantage in this
point, from the examination of etchings of the Italian
and Dutch landscape painters, such as Claude Lorraine,
Canalette, Du Jardin, Rembrandt, Both, Ruysdael, and
others, which will conduct him on the right path; and
will sufficiently warn him to avoid the low, vague, and
unscientific style of Moreland, and his followers, the
makers of drawing books, who have been long so success-
ful in corrupting the taste of the amateurs of land-
scape.

In drawing with Indian ink, bistre, or any other si-
lar colour, always presupposing a correct and well
defined outline, the large shadows will be laid in first,
marking out the general effect or chiaroscuro of the whole;
the shadows of the smaller objects will follow;
and the finishing touches will be given to each part,
according to the strength of colour and style of hand-
ing, which the situation and character of each may re-
quire. In laying a large shade, there is considerable
difficulty to the beginner, in keeping it smooth and free
from those marks and stains, which arise from stopping
in the middle of the operation, or working with too
small a quantity of colour in the pencil, and thereby
allowing the edge of it to get dry before it be finished:
this may be avoided by beginning at the left side
of the part to be wrought upon, going regularly on with
a full pencil, and leaving no part so long as to give it
time to dry at the edge. The pencil should be of a size
proportioned to the space to be covered; and the shade
should be laid on as smooth and equal as possible, with-
out leaving any more of the tint than is sufficient to
cover it. This ought to be particularly attended to in
skies, where any defect of this sort is so conspicuous
and irreremediable.

In sketching from nature, the most essential requi-
sites of which are characteristic, spirited, and cor-
cet delineation, and a slight but expressive mode of
shading: the outline is often done with a pen, and this,
either with Indian ink, or a brown colour; this last,
when the shading is done with Indian ink, gives a fine
effect when applied to the sketch. A solution in oil of
terpenine, of the bitumen called asphaltum, is sometimes
used in this way; and in those subjects where bold-
ness and freedom, rather than minuteness of de-
tail, are required, such as large trees, rocks, &c.
it has a fine effect. The paper should be rather of
a rough and absorbent quality, such as the finer sort
of cartridge paper, as it prevents blotting, to which this
solution has a great tendency: it should be kept in a
phial, and the pen dipped in it when wanted.

The tinted paper already mentioned, is very useful in
slighter works, whether sketches from nature, or those
studies for the composition or effect of larger pictures;
as the chiaroscuro may be made out, with great ease
and rapidity, either with black chalk or Indian ink,
and the lights put in with white chalk, or with perma-
nent white, put on with a hair pencil. This is the oxide
of zinc, ground in the usual way, and mixed with the
mucilage of gum arabic; it is sold in the shops in cakes,
and is infinitely preferable to white lead, or flower white,
which, from their tendency to return to the metallic
state, and to become black, are totally unfit for use in
drawing in water colours. In this way, those brilliant
and transitory effects of sunshine, which are so striking
in nature, and give such interest to a picture, may be produced with the utmost ease and delicacy.

The art of drawing in water colours, which, till within these few years, had never been considered in any other light than as an expeditious method of making sketches slight, has been recently carried to the greatest perfection by the landscape painters of the English school.

The method that was followed in its beginning, was to make out the effect and finishing by what was called a neutral tint, and afterwards to give each object its proper colour and depth, by washes of the several tints over the original one. This mode, though not adapted to give that strength, solidity, and variety, which the recent improvements of our contemporary artists have shown that drawing in water colour is susceptible; yet as the process is more simple than any other, it is on the whole better calculated for beginners, who, when they have acquired sufficient facility in it, and knowledge of their materials, may extend their researches to the other methods, which we shall afterwards take notice of.

The neutral tint, which each artist made up, like every other tint, in his own way, was by some composed of blue, lake, and gamboge; blue, lake, and Indian ink; or blue, lake, and sepia. The student will begin by a wash of the grey over the distance, leaving out those parts which are quite light; and as a more soft and delicate effect will be produced by repeating the process several times than by doing it at once, the tint will be made lighter at first than the effect intended. In this manner, every part of the work, from the most remote distance to the face ground, will be done; with this difference, that the proportions of the various colours composing the neutral tint will be altered, according to the distance of the several objects. Thus the lake and blue, which produce the aerial tones, will be increased in the distant objects, altering the tint from a coolish grey for the distant to somewhat of a warm brown for the nearer objects; and the proportion of the sepia, umber, or whatever it may be, will be greater for the face ground objects, leaving the paper untouched in every part where clear light is required. When the broad shadows have been thus laid in, and the general effect of the chiaroscuro produced over the whole picture, the more minute parts will be made out by darker touches of the same tint, of which each shadow is composed.

The sky.

The student will next begin to the colouring of the sky. The blue will be composed of Indigo, to which a small quantity of lake will be added; and the tint of the clouds will be made up of blue and lake, which will be modified by the addition of madder brown, sepia, light red, &c. according to the effect intended. In laying in a flat tint of blue, or any other colour where smoothness and equality of surface is desirable, the paper should be dampened with clean water laid on with a broad thin brush, and as much of the water taken off by pressing the paper with a clean towel, or a piece of blotting paper, which will leave it in a state sufficiently damp for the purpose. This will be found of great service, particularly when a gradient from a darkish to a lighter blue, or, as in morning or evening, from blue to a warm yellow, orange, or red colour, in the horizon, is required. When these colours are fixed by the drying of the paper, if the warm tint is not sufficiently strong, it may be increased to any depth, by another wash of the same colour, which may be blended into the blue with a little clean water. The clouds and whole drawing may likewise get a wash of the same, and the necessary variety of blue on their different parts may be afterwards given.

The greens will be made up of sepia and gamboge, and may be diversified at pleasure, according to the tint of the several objects, by the addition of indigo, brown pink, or burnt terra di sienna. The buildings, rocks, trunks of trees, &c. may be done with a light tint of burnt umber, and those more distant with burnt sienna, which will form a ground for any variety of cold or warm colour which it may be necessary to put over them; and these may be varied to any extent, by tints composed of blue, umber, lake, burnt sienna, sepia, yellow ochre, and the like.

As, by the repeated washing of the several tints over the grey, the sharpness of the several parts will be considerably injured, it will now be necessary to retouch, with great care and delicacy, any part that may be defective in this respect: the distance with warm or cool shades of grey, according as it may be wanted, and the face ground with brown, made up with sepia, and perhaps the addition of lake and blue, which will complete the process. But in this stage of the process, care must be taken to avoid cutting up this effect by a dark and harsh mode of touching.

In painting a sky, it is often desirable to give more sharpness and decision to the forms of the lights than the ordinary processes of merely leaving them out permit, such as on the edges of the clouds, the form of the sun or moon when they occur, or the rays of light bursting from behind a cloud; accordingly various substances have, at different times, been used to stop up the lights, as in aquatinta engravings, and prevent the tints from adhering to the part of the paper where it has been put on; and when they were finished, to take off the substance employed, leaving the paper perfectly free from any tinge of the colour: for this purpose, the yolk of eggs, and compositions of white lead and olive oil, or white lead and mastic varnish have been used, the former of which may be taken off by Indian rubber or the crumb of bread, and the latter with the oil of turpentine, or spirit of wine rubbed over them with a brush. But of all the substances that have been used for this purpose, there is nothing that unites so well the advantages of utility and convenience, as pipe clay scraped upon a plate and mixed up with water to a due consistency; the touches being put in with this, by means of a hair pencil, and allowed to dry, the tints may be washed freely over it, and when rubbed with bread the lights will come out with the utmost sharpness, and will have more the appearance of being touched over with distemper or some opaque substance, than of any thing that water colour painting could be supposed capable of producing.

The preparation of the paper.

The proportions of water colour painting of great importance in water colour drawing. The best drawing paper, as it is manufactured, is totally unfit for finished drawings, from the smoothness of its surface: it must therefore be well dampened, and the polish taken off by rubbing it well with a wet sponge. By this means, the paper will acquire a degree of roughness and absorbency, which will afford great assistance in giving the necessary solidity and depth; which were qualities unknown to water colour drawing till this process of treating the paper was adopted.

Another method, which is next to that of the neutral tint in simplicity, is, to make up the shadows of distant objects with indigo and Indian red; of those that are nearer, with Indian ink; and the face ground with shades of Indian ink, and touched up in the minute parts with
sepia. Over these the tints of the different objects are put on, as already mentioned.

By mixing with the colours of the sky, and the grey tints of the distant shadows, a very small portion of permanent white, great dilution will be made to the solidity and apparent air of these parts. The quantity of white must be excessively small, and when in due proportion, will not be discovered by making any difference on the general appearance of the object, and these tints may be washed over as often as the effect may require; and this may even be practised both on the lights and shadows in every part of the drawing.

Sometimes a drawing is carried through its different stages without the use of any middle tint, by putting on the lights and shadows of the different objects at the same time; the lights, of course, of their proper colour, and the shadows composed of tints, wherein the colour of the object and the greyness of shadow are combined, and blending them into each other when wet; and these tints, both in light and shade, may be retouched with other tints, according to the variety and depth required in the several parts.

The practice of some artists, is to put repeated washes of the pure colours singly, making out every part with greater brightness than is intended, and then to wash down with grey or neutral tints each object, according to its relation to the whole; and these tints will be much improved by the addition of the smallest quantity of permanent white, as already mentioned.

Another method much practised, which has a good effect, is to lay over the different objects with the tints of their respective shadows, without leaving any light. The light will be afterwards taken out by putting on touches with clean water in a hair pencil, according to the form of the lights required, and rubbing the paper with soft bread till all the colour be entirely brought off the parts, and the lights will be put over on those parts where the tint of the shadow has been taken off. In this way, the lights of such objects which, from the complexity or peculiarity of the forms, it would be tedious and difficult to leave out, as in the foliage and ramification of a thin tree appearing light against a dark object, or in analogous cases, will be made with the greatest minuteness and precision. This may be extended to almost any object in any part of the picture; and in the foreground, in particular, the degree of roughness which it gives, (which is indeed a stumbling block to the ignorant,) is of most essential advantage, in giving a variety of surface in rocks, trunks of trees, &c.; and these tints may be washed over as often as necessary, till the parts are brought up to their proper tone, and if found not light enough, the process of wetting with the hair pencil, and rubbing with the bread, may be repeated as often as occasion may require. The lights on the surface of a piece of water, or the smoke of any distant fire, &c. will be much assisted by touching them up with permanent white.

When the drawing is found to have received too much local colour, thereby depriving it of the requisite effect of air, it will easily be brought down to the utmost delicacy of tint, by washing it over with a great quantity of water and a flat tin brush; taking care that all the colour that is disengaged from the paper be properly washed away, so that the brilliancy of the lights may not be injured by any of the dark colour. When the drawing is brought to a sufficient delicacy of effect, and has become perfectly dry, any deficiencies in sharpness of form or brightness of colour, may be supplied by retouching with the several colours.

The sponge is likewise an important auxiliary to a painter in this department of his art; as when any object has received a tone of colour, or even a form which he would wish to change, he may proceed with the wet sponge till he has got it sufficiently lightened, or even, if necessary, entirely taken out; and this will be no detriment to the general appearance of his drawing, as the paper is roughened already, as directed above, as much as it can be: it is obvious, however, that unless the paper be of considerable thickness, it will not admit the repetition of this process very frequently.

When the shadows of any objects, more particularly in the distance, have acquired too great a degree of brightness, it may sometimes be reduced by a method, the efficacy of which would not, à priori, be suspected; namely, by a thin wash of yellow ochre over the part, and sometimes a very thin wash of permanent white, or even, in certain circumstances, of pipe clay, will have the same effect.

We have already elsewhere cautioned the painter against the use of white lead, in any shape; as, from its opacity, and the blackness that it in a very short time acquires, it is altogether unfit for water-colour drawing.

In making out the effect of the reflections of objects in water, (always presupposing the knowledge of perspective necessary, to give each object its proper form and situation,) in order to represent the effect of softness and delicacy, so beautiful in nature, produced by the blending of the tints of one object into those of another; the paper should be damp all over the part to be wrought upon, in the manner already prescribed for doing a sky; and the broad masses of colour, according to the tint required for each object, will be laid on. The dampness of the paper, aided by the roughness of its surface, will give a softness and liquidity to the water, which could not be produced in any other way; and this process may be repeated when it has dried, as often as expedient, till the necessary effect be produced.

On the foreground, when a few touches of a very dark colour are required, indigo, and a little lake, will form a tint of the deepest tone possible, which, however, must be used with great caution, in order to avoid harshness.

As coldness is one of the most disagreeable defects that a picture can have, it will always be advisable to paint on rather a warm key; and this, when carried to any excess, may be much more easily corrected, by the introduction of a few cool greys in the shadows, than to give any appearance of warmth when the effect has got into the opposite extreme. This coolness will be best given, by a mixture of madder, lake, and indigo; and a very small quantity of this tint will be sufficient for the purpose.

We have made no mention of Prussian blue, which though a more brilliant colour than indigo, is not so well adapted, and has indeed lately been almost totally expelled from water-colour drawing. There is one serious disadvantage to which it is subject, namely, that in the grey already mentioned, made up of blue and Indian red, if the Prussian blue were used instead of indigo, the action of light upon it would soon discharge all the blue, and leave nothing but the colour of the red. This ought to be most particularly attended to, as in a few days the whole tone of the drawing would be completely changed.

The paper, before beginning to work on it at all, should be fixed on a drawing board, and made as flat as poss-
DRAWING.

Distemper, or body colour.

Besides the water-colour drawing which we have just treated of, there is another which is called distemper, or en détrempe, body colour, which differs from the transparent water colour in this, that, instead of putting on the colours in thin washes, one over the other, and diluting them with water, the middle tints are mixed up to the oil, and put on in thick opaque masses, lightened by adding white, and the lights and shadows touched on them till the effect required is produced, in the manner of oil colours. This method was much practised by the Italian and French landscape painters, more particularly those who painted architectural subjects and theatrical scenery.

But as few of the colours withstand, in this way, the action of heat, and as the surfaces are also easily damaged, it is best fitted for ornamental purposes, such as the decorations of rooms and theatrical scenery; particularly as, having none of the gloss which renders oil painting so marvellous for this purpose, it may be seen equally well in whatever direction the light may come upon it. The pigments commonly made use of in distemper painting, are fine chalk, zinc white, yellow ochre, Dutch pink, gamboge, raw and burnt sienna, light red, burnt umber, lakes, and indigo; to which number may be added, almost all those colours that are in general use, either for painting oil or water. They are to be ground up with water, and wrought with size.

Drawings in this way are commonly done on paste-board, made of two or three plies of paper, sometimes of paper pasted down on linen strained in a frame, and for theatrical scenery of strong coarse canvass. Paper that has rather a rough surface, and has in some degree what is called a tooth, is best calculated for this purpose. When the outline is sufficiently marked, in order to give the necessary smoothness and finish to the sky, which ought to be done at once, as there is some risk in attempting to retouch a sky, the paper must be wet all over with a hair pencil, which will keep it sufficiently damp till the sky be finished. The blue for this purpose is indigo mixed with white, till it be of a light enough tint. Blue verditer is sometimes used. A beautiful grey will be produced by the mixture of indigo and burnt umber, lightened to the tint required by the addition of white; if it be too purple, a little yellow may be added. But the student, who must have some previous knowledge of the effect produced by different combinations of colour, will soon be able, without much advice, to mix up his tints in this way, as well as in oil or water colours. There is one disadvantage to which this method is exclusively subject, namely, that the colours when wet have a totally different appearance from what they have after they have dried; but this difficulty a little practice will soon remedy.

In painting architectural subjects, for which purpose distemper is well calculated, the painter has advantages which neither oil painting nor water colours possess; he can give a sharpness and precision to the most minute members, as the lights and shades of those objects which are composed of straight lines, such as cornices and other moldings, may be ruled with the square, the colour being put on either with a fine hair pencil, or, when great minuteness is required, with a steel ruling pen. In the sky and distant parts of the picture, in order to give the necessary effect of air, the middle tints must be made up to such a consistency as to cover the paper entirely; but in the nearer objects, where this is not required, the colours may be mixed up with a smaller proportion of white, and put on with thick and semi-transparent: this will give a depth to the tones of the shadows; take off that chalkiness which it is so difficult to avoid in distemper painting; and, in order to increase the depth and variety of tone in the foreground objects, so necessary to the good effect of every picture, the process called glazing, so well known to painters in oil, will be found a most useful assistant. Of glazing.

It consists in this, that when the middle tints and lights are put on with the opaque colour, and allowed to become dry, transparent washes of the same colour, water colour are put over them, according to the quality of tint and depth of shadow required. Thus the green will receive a great accession of strength, freshness, and brilliancy, by a thin transparent wash of gamboge and sepias, which may be altered or modified by the addition of any other transparent colours, such as lake, indigo, burnt terra di sienna, umber, or the like; and tints composed of the same colours, by varying their proportions, may be produced fitted for every sort of object. As the washing over any tint with another must necessarily more or less impair the sharpness and spirit of the touches, it may be wrought up to the proper strength and firmness by dark touches of any transparent tint, best suited to the colour of the object.

The size, which ought to be made of the best glue, should be of such a strength and consistency, as to be permanently fluid at the common temperature of the atmosphere, 60°; when much stronger than this, it gives darkness to the colours, and when weaker, does not bind them together, so as to prevent them from rubbing easily off.

The colours when ground are to be kept in pots; and to prevent their drying and becoming hard, and so requiring to be ground again, they must be kept constantly covered with water, and occasionally stirred up with a small piece of wood.

Sometimes drawings in distemper are varnished, which gives them very much the effect of oil painting: but the brilliancy of the lights is entirely destroyed by this; a defect for which the amazing depth, variety, and clearness of tone which the varnishing produces in the shadows, by no means compensate. By rejecting those pigments, the basis of which is chalk, such as English and Dutch pink, verditer, &c. and using only those which have a good body when ground in oil, the tone of the picture will not be so much lowered; but it does not seem possible to give a proper effect to a picture in this way, without touching it up with oil colours.

It has often been suspected, and that with great appearance of probability, that it was the practice of the great masters of the Venetian school, to lay in the ground work of their pictures in distemper; and, by glazing and touching them up with oil colour, to bring them up to that astonishing brilliancy which, with few exceptions, is to be found only in the productions of that school. (P. 4.)
DRAWING INSTRUMENTS.

Drawing instruments may be divided into several kinds: First, Those for drawing lines, as pens, pencils, crayons, and steel pens. 2d, Instruments for guiding or directing the above, as rulers for drawing straight or slightly curved lines, compasses for drawing circles, the elliptograph for drawing ellipses, and the geometrical pen for producing a great variety of curves. 3d, Those which are used for marking or setting out distances, or dividing them, as compasses and divided scales, sectors and protractors; also instruments for dividing circles and ellipses.

Case of Instruments.

It is customary with artists, whose operations are connected with mathematical designing, to provide themselves with a selection of drawing instruments, containing such as they find, by experience, are most frequently wanted, and best adapted to their particular purposes. What is called a complete case of mathematical drawing instruments, such as may be obtained at almost any shop, contains the following articles: A steel drawing pen, the handle of which unscrews, and has within it a sharp steel point, for the purpose of pricking centre points. A black-lead pencil, with a silver ferrule or top formed to the shape of the point of a knife, but made with a smooth blunt edge, for the purpose of scratching or tracing lines upon the paper: these lines are permanent, though not visible without particular examination. A pair of compasses for measuring distances. Another pair of compasses, of a larger size, for the same purpose, and also for drawing circles; to effect this, one of the legs is fitted in a socket, and fastened by a screw, to admit of removal for the purpose of applying other legs to it: these are, a steel pen leg, for the purpose of drawing circles in ink; a leg adapted to hold a piece of black-lead pencil, for describing circles in pencil; also a dotting leg, which is a small wheel, with several points, something resembling the rowel of a spur: it is fitted to revolve between two blades, like those of a steel pen, and these, in the same manner, formed out of the leg, which adapts to the compasses. The space between the blades being filled with Indian ink, and the wheel rolled upon the paper while the compasses turn round, its points make equidistant dots in the circle which the compasses describe; and as the points of the wheel pass through the drop of ink which is held between the upper part of the two blades of the instrument, they are successively replenished with ink. A small pair of bow-compasses: these are small compasses, with a pen leg permanently attached to them, so that it cannot be removed: they are useful to draw very minute circles. A sector, which is a scale containing many lines of mathematical divisions, which are very extensively useful for trigonometrical operations. A parallel ruler, for drawing straight lines parallel to each other. A plain scale, which has lines upon it graduated with equal divisions, of different values. Also a protractor, or semicircle, divided into degrees, for laying down angles. All these instruments are so well known, that it is needless to give a more minute explanation of them, particularly as those which are sold in such kind of cases are not made on the best construction, having many defects, which it has been the study of several artists to remedy.

Pencils.

In our observations on instruments, we shall begin with those which are employed for drawing lines; and of these, black-lead pencils come first to be mentioned. They should be of very pure lead, without any mixture of hard particles. The hardness of its substance should be adapted to the purpose for which they are to be used: for mathematical drawing, the lead should be hard, so that it will cut to a fine point, and preserve it sharp for a considerable time without sharpening, and at the same time it should mark with so little pressure, that it will not penetrate or indent the paper. The mark it makes should be quite superficial, that it may be totally obliterated by a light application of the Indian rubber. This is a very essential requisite in a pencil; for if the paper requires much rubbing to clean off the pencil marks, its surface will be injured, and prevent any good finishing or colouring upon it.

Some pencils are made by reducing the black lead to powder, and recomposing it by the admixture of some glutinous substance. By this means they separate the impurities from the lead, and make tolerable pencils; but these do not stand to so good a point as others made from solid lead, when the same is of the best quality. Messrs. Brookman and Langdon of London, (28, Russel Street, Bloomsbury,) have invented a process, by which they purify the lead, and produce pencils of any required quality. With respect to the hardness, these makers distinguish them by the following marks: HH, very hard, for engineer or shipbuilders' use; H, rather less hard, for architects, who require less accuracy, but more freedom for sketching in ornamental parts; F, fine drawing pencils, are of a middle degree of hardness—these are not intended for ruling lines, but for drawing figures, landscapes, &c.; B, black for shading, are rather soft lead; BB, extra black for deep shadowing; and BBB, are prepared as black as possible for shadows. All these marks are of a very superior kind, having the requisites we have enumerated for good pencils, particularly the HH, which stands to a point so long, that cutting the pencil with a knife two or three times in the course of a day's work will be sufficient. The point will frequently wear so as to draw rather a broad line; but it is better to restore the point by rubbing it on a piece of paper, and at the same time turning it round, than to attempt cutting it every time with the knife. For this purpose, a piece of the very finest glass, or emery paper, is very useful. The point so formed should not be too acute, or it may break.

Steel pens, for drawing lines in ink, are made in many different forms; but they all consist of two blades of steel, so fitted together that they have a tendency to spring open from each other. They have a screw, or equivalent contrivance, by which the points can be closed together to any required degree, leaving a small opening between their points, through which the ink flows down from the upper part, where a drop of it is retained. When the pen is used, it must be fairly applied to the edge of the ruler, and drawn along it, taking care to hold it so that both points touch the paper at once, or it will not draw an even line. It will act best if it is rather held in an inclined position, in the direction of its motions; it then leaves upon the paper a breadth of ink equal to the opening between the points, and this may at pleasure be increased or diminished. The points of the pen should be rather round, that they may not penetrate the paper; but in the thickness,
they should be quite sharp at the edge, otherwise they will not make a regular line. Fig. 24, is a very good kind of steel pen, consisting of two steel blades, put together by a rivet at \( a \), and secured by a brass or silver cap, screwed upon the upper end, where the extremities of both blades being laid together, are cut into one screw, as shown at \( n \), Fig. 25. The lower part of the blades has a milled screw \( d \), which draws them together, to adjust the distance of the points \( e \). When the pen requires sharpening, the screw \( d \) is taken out, the cap \( b \) screwed off, and then the two blades may be opened out like scissors, on the centre rivet \( a \), as shown in Fig. 25, to expose the inside surfaces of the points \( e \). The points of all pens should be hardened and tempered; but they will in time grow blunt at the edges, by constant use, and must then be repaired, by rubbing them upon a hone to sharpen the edges again. In doing this, great care must be taken that both points are made to correspond both in length and breadth. Some pens are made with a joint to unite the two blades together, as shewn applied to the compasses, Figs. 3 and 8, and these have a small spring between them, to force them open. The screw for adjustment is the same as the former. The pen of the pocket compasses, Fig. 7, is adjusted by means of a sliding ring \( f \) fitted over the two halves of it, because there is in this case no room for a screw, when the pen is inserted into the hollow of the leg of the compasses. By sliding the ring down towards the point, the pen is closed up; or, by sliding it upwards, the points are suffered to open. The same mode of adjustment may be used for a drawing pen.

Fig. 23. is one of Mr. Donkin’s patent steel pens, which is intended for writing; but as it is a useful instrument for drawing, we introduce it here. The other kind of steel pen is as perfect as can be wished, for drawing straight or regularly curved lines, where some guide is used for it; but it will not do for those lines which are to be drawn by the hand, unassisted by a ruler, or other means of directing the pen. It is the usual practice to draw such lines with a crow, or goose quill pen; but they can be much more neatly executed by Mr. Donkin’s, which is the best writing steel pen that has appeared. The nip or point consists of two pieces of thin steel plate \( a, a \), put together nearly at right angles to each other; and the part where they meet is mitred, to make a joint for the slit of the pen, which is quite close, except when the pen is writing, and then the pressure bends the blades, and causes the joint to open sufficiently to deliver the ink; therefore, in proportion as this pressure is increased, the line becomes broader, in the same manner as the common goose quill pen, but with the advantage of being much more elastic in the blades of the nip, because they are filed very thin just above the point. The pen writes finer than a quill does, except the minute after being mended, because the points are made of a very hard substance; and when once made up carefully to write or draw fine, will not speedily wear out. The two pieces of steel \( a, a \), composing the nip, are united, by being soldered to a piece of metal, and this fits in the silver tube \( d \), which forms the handle. The shape of the point which writes is not easily described; but may be considered as similar to the point of a quill writing pen of the best form, except that the two pieces which form the nip are not portions of a cylindrical tube, but two flat plates situated at right angles to each other; and it is this circumstance which gives it the superiority over other steel writing pens, because the flat sides are very elastic, and bend freely; but a portion of a tube cannot spring readily, however elastic its substance may be.

The thin plane before mentioned, just above the nip, is reduced by filing from the inside, to allow the points to spring; and is of further use, to form a slight cavity where the ink rests, and is ready to pass down to the paper the instant the slit of the pen is opened, by pressing on the paper. The handle of the pen is made of three tubes, \( d, e, \) and \( f \), which shut one into the other, for portability; but when drawn out, as in the Figure, form a sufficient handle to write with.

The point of the pen, as shown separate at \( z \), draws out of the lower end of the external tube \( d \), and being inverted, and thrust in, is secure from injury; and thus the pen requires no other sheath when carried in the pocket. When a pen of this kind is used for drawing, its point must be very carefully made sharp, by rubbing it upon an oilstone, and it will draw better than any other for such lines, as the steel drawing pen will not execute.

Rules for accurate purposes should be made of steel, or brass; but as these are liable to contract, tarnish, or rust, and then soil the paper, wood and ivory are preferred for general purposes; still no artist should be without accurate brass or steel rulers of considerable length, to lay down his principal lines, and to verify his smaller rulers. A convenient standard brass ruler may be two feet and a half in length, and have inches and decimals accurately divided upon one edge of it, and decimals of a foot upon the other. One edge should be bevelled or made sharp to draw lines by, and the other left the full thickness of the ruler, but both should be very exactly straight. When rulers are made of wood, it should be of a hard texture, such as mahogany, box, beef wood, or ebony, and pieces should be carefully selected which have a clean straight grain, as these are the least liable to warp. The edges which are to be used to draw the pen against should be always bevelled, and very smooth. To verify the edge of a ruler, a very fine line should be drawn by it, taking great care to hold the pen perpendicular, and apply it fairly, then move the ruler to the opposite side of the line so drawn, and reversing it end for end, that the same edge of the ruler corresponds with the line, examine if it does exactly correspond in the whole length, which it cannot, unless both the edge and the line are very straight; because this mode of trial doubles the quantity of the error, and therefore renders the smallest deviation apparent. Ivory is the best substance for ivory, small rulers and divided scales, because being so smooth, the drawing pen slides freely against it, and draws beautiful lines: The divisions also, when filled with black, are more apparent to the eye than on any other substance. The only objection to it is, the liability to warp on every change of weather; but if carefully selected, some pieces may be found to preserve a very straight edge under all circumstances. The shape of the tooth among those, which are cut from the centre of the tooth, having the grain of the ivory radiating each way from the centre of the ruler to the edges, to appear something like the feather of a quill; in this case, both edges being of similar texture, they expand or contract equally, by the moisture or dryness of the atmosphere, and therefore do not change their figure. Scales of this kind, and about 12 inches in length, are extremely useful when divided, as shewn in Fig. 15. These are called plain or plotting scales, and are divided into 10 and 20, 30 and 40, or 50 and 60 per inch, as the artist requires. They are much more accurate for drawing than a scale made on the paper, and more convenient, because the divisions coming to the edges of the scale,
distances can be marked off upon the paper without the compasses.

For the use of surveyors, Mr. Farcy has contrived a small offset scale, Fig. 16, which transfers the division of the long scale to the paper very readily. The offset is made exactly twice as long as it is broad, and has a line drawn across it in the middle, which, when used, gives it into two squares from which one side is zero. It is graduated with divisions of the same value as the long scale, which it is to be used with. These divisions are numbered both ways. From the centre, the ends of the offset are exactly perpendicular to the sides; and when it is applied, as in the Figure, to the edge of the scale, which is held fast down upon the paper, while the offset slides along against its edge, any number of short lines may be drawn by the edge of the offset, and will always be parallel to each other, because they are all perpendicular to the line of the ruler. The divisions of the long scale show their distance from each other. For lines which do not exceed three inches in length, this is more convenient than any other kind of parallel ruler; but its principal object is to project points on irregularly curved lines, such as $a \times y$, to represent brooks, fences, &c. in maps. Suppose the right line $a b$ to represent one of the straight lines of the survey which has been measured upon the ground, beginning at $a$, where the curved line intersects it, and proceeding to $z$, 50 feet, yards, or links of the measuring chain, the perpendicular, or offset, from the line to the hedge was found to be 16 of the same denomination at $z$, which is 65 from $a$, the perpendicular offset to the curve line is 28; and thus by a number of offsets, the whole curve is determined. The usual method of plotting this is, lay the scale, Fig. 15, to coincide with line $a, b$, and mark off every division where an offset was taken; then at these points draw perpendicular lines, and upon them mark off the length of the several offsets. By the offset scale, Fig. 16, all this is effected at once. Thus hold down the long scale as in the Figure, so that when the offsets slide against it, its centre line will always pass over $a, b$; also when the edge of the offset is at the commencement $a$, it must likewise be at zero of the long scale. Now slide the offset till its edge comes to the division 50, which is the first offset, and here mark off the division 16 upon the offset for the point $x$; then slide it to 65 on the long scale, and mark off 28 for the point $z$; and so on for $y$ and any number till the curve is completed. This offset scale will likewise be useful to the mathematician in setting out any curve, which is expressed by the ordinate and abscissa, by calculating from the equation of the required curve. Let him make a table, showing the relative lengths of several ordinates to their corresponding abscissae, and he then proceeds to project the points as before described. To the naval architect it is very serviceable for projecting the different sections of a ship, when their lines have been determined in numbers by calculation.

Parallel rulers are of various constructions. The simplest and most common consists of two light rulers $A B$, Fig. 12, united together by brass links $a, b$, of equal length; and the two points on each ruler, where these are jointed to them, being also of the same distance, forms a parallelogram, the joints of which moving freely, the two rulers may be separated, but will always be parallel. In practice, the edge of the ruler $A$ being placed to coincide with any line, the ruler $B$ is held fast down upon the paper; and the ruler $A$, when opened out to any distance from the other, will always

Mr. Eckhardt's parallel ruler.

The wheels are slightly indented upon their circumferences, that they may not slip upon the paper; and being made exactly of the same diameters, they carry the two ends of the ruler forwards an equal quantity, and therefore the edge moves parallel. The distance which the ruler moves is also measured at the same time, by means of two small ivory wheels $e, e$, which have divisions upon them, so proportioned to the size of the ruler, that each division is equal to one-tenth of an inch of the ruler's motion, and these may be subdivided by sight. The divisions are read against an index, fixed upon the ruler at $d$, and the same piece forms a centre for the pivots of the axis of the wheels.
124 DRAWING INSTRUMENTS.

Drawing

Instruments.

This invention is better in theory than practice; the rollers being liable to be diverted in their motion by the least irregularity on the paper, and it therefore requires to be used with the greatest care, otherwise it will not be so accurate as the common instruments.

Of all methods of drawing parallel lines, the drawing board and T square is undoubtedly the best. This, as commonly used, is too well known to require any description; but in Fig. 19, a square and drawing board is shewn, having some improvements. The edges have slips of box, or other hard light-coloured wood, inlaid; and these being divided into those scales which are most frequently required, will be found extremely convenient to work from, without requiring compasses. The divisions on the adjacent sides of the board are of the same scale; but those upon the sides which are opposite to each other are of different values. This renders the use of the board more extensive, because it is the two adjacent sides only which are used for the same drawing; one being used for the measurements of lengths upon it, and the other for heights of elevation. The drawing board is represented to be fixed down at the angles by pins with a large flat head, such as is shewn in its full size at Fig. 4. The point is sharp, and is pressed down into the board. Another method of holding the paper, is shewn in half its full size in Fig. 18. a is a steel screw, passing through the board with a thin, flat, conical head, which is very exactly fitted into a brass cell b, fixed fast into the wood of the drawing board. The screw is tapped beneath, and has a nut c upon it, to draw it down. The Shank of the screw is made square, that it may not turn round in the cell b. The edge of the paper being introduced under one side of this conical head, and the nut c turned, it draws the head a down upon the paper, and pinches it tight into the cell, so as to hold it fast; and at the same time makes no elevation above the surfaces of the paper, which can obstruct the passage of the square or other rulers over it. The stock A of the square AB, Fig. 19, is as usual made of three times the thickness of the blade or ruler B; so that when either side is turned upwards, the stock presents an edge projecting beneath the plane of the blade B, which being applied to slide against the edge of the drawing board, keeps the ruler in all situations perpendicular to it. The upper of the three projecting edges, which is seen in Fig. 19, at A, is not formed of the same piece as the other part of the stock, but is a thin ruler fitted upon it by a centre-screw a, and has another screw b passing through a curved slit to fasten it. By revolving this screw, the inside edge of this ruler can be made to incline, at any required angle, with the edge of the stock on which it is fixed, and with which it is now represented as coincident. There is a semicircular part at b, which is divided into degrees, and reads against a vernier, divided upon the lower part of the stock; and by this angle is measured. The use of this moveable side to the stock is to draw lines inclined to others at any required angle, or indeed to answer all the purposes of a protractor. Thus having with the edge of the ruler B of the square, as it stands in the Figure, drawn any line, set the moveable part of the stock to the required angle, by the divisions at b; then turning the square the other side upwards, and applying it to the edge of the board, the ruler B will make the required angle with the former line, and also with the edge of the drawing board; and by applying the square to the adjacent side of the drawing, a line may be drawn at right angles to the inclined line.

This is called a square with a bevel, and is very useful for drawing long lines inclined to the sides of the board. But for short lines, the instrument, Fig. 17, is more useful. This is a small bevel or ruler, jointed like a sector, with two limbs moving on a tight joint; the edges are bevelled towards the inside, for ruling against. In use, it is laid against the edge of the square, as at M, Fig. 19, and may be opened to any angle; then by sliding it along the edge of the ruler B, or moving the ruler up or down across the width of the board, the edge of the bevel may be brought to draw in any part of the paper; and having drawn a line in one place, will draw another parallel to it at any distance. It will also draw lines anti-parallel, that is, reversed, or making the same angle in an opposite direction. This is done by reversing the bevel, as shewn by the dotted lines; and will be found extremely useful for drawing the opposite sides of the roofs of buildings, or any other inclined lines. The same bevel when applied against the edge of a ruler, as at Fig. 17, will divide a line into any Fig. 17. required number of equal parts. Thus, for instance, suppose the space between the points a and b is to be divided into seven equal parts. To do this by the bevel, lay the inside edge of one leg D, to cross the line at one of the points, viz. a; then place the edge of the long ruler 15, behind it, and hold it fast down, that the bevel may slide freely against its edge, but without deviation from its direction. Now open the bevel to such an extent, that when the division numbered 7. on the inside of its limb E, is brought, by sliding the bevel against the ruler, to intersect the line which is to be divided, the intersection shall be at the other extreme point of the space to be divided, viz. at b. The instrument is now prepared; and to mark the divisions, slide the bevel against the ruler, till the division No. 6. intersects the line. There draw a mark by the edge of the bevel, cutting the line a b, as at g; next bring the division 5. to cut the line, and mark No. 5; and so of all the rest, and the line will be divided into seven, as required. It is plain, that if it had been required to divide it into seven and one-third, instead of seven, the same process would have effected it, by only preparing the instrument, by opening the bevel so much more as to bring the division seven and one-third to cut the line at the point b, instead of seven. It is for these fractional numbers the instrument is chiefly useful, because it is so difficult to do them by the compasses.

Dividers, or measuring compasses, are shewn in Fig. 5. They have nothing particular in their construction, which is not apparent from inspection, except the addition of a clamp and adjusting screw, to adjust and preserve the opening of the compasses. This consists of a piece of steel A a, which is formed to a screw a at one end; and the other has a slit or opening made through it, for the reception of the milled-head screw d, which screws into the leg of the compasses, and thus with a clamp binds the steel A a fast against it. B is a milled-head nut, into which the screw a is received. This nut has a shoulder and a neck, or small part, which is fitted into the socket e, formed of a piece of brass fastened to the other leg of the compasses by a round pin, which is adapted to a hole through the leg, and secured by a nut, or screw, on the other side, from either drawing out or shaking; and the nut B is so fitted to its socket e, that it will not draw out, though it turns freely. The utility of this clamp is very great, for measuring accurately, or dividing lines or circles into a great number of parts. When the screw d is loose, the compass joint can be opened or shut on their common joint, as easily as any common pair; but clamping the screw d fixes them quite fast. Still they admit of a delicate
adjustment, by turning the nut B, which gives a slow progressive motion to the screw a, and thus to the points. This we consider as the best pair of dividers we have seen, for the clamp is very steady, and quite convenient to use when great accuracy is required; but for ordinary purpuses, it may be quickly removed altogether, by taking out the screw d, and the socket e. The dotted lines shew another sort of clamp, which is simply a curved piece of steel plate, with a slit through it, for the reception of the screw d, which is tapped into the leg of the compasses. The other end of the clamp is fastened to the opposite leg by a single screw. This makes a very effectual fastening, to prevent the distance to which the points of the compasses are opened, but is not so good as the preceding, because it wants the adjusting screw.

Fig. 1. is a small pair of dividers. These have no joint, but are cut out of one solid piece of steel, and always tend to open by their own elasticity. They are shut up and adjusted by the small screw a, which is tapped into one leg, and passes through a hole in the other. The upper part of the compasses forms a handle for them. The points b and c are made to screw into the legs, in order that they may be taken out to sharpen them upon a hone; and also because the points require to be made of cast steel, and left of a hard temper, whilst shear steel, and of a spring temper, is more fit for the upper part, as it requires elasticity and toughness. These form a most useful instrument for setting out a great number of small equal divisions, not being liable to alter whilst in use; and the screw gives the means of adjusting them very accurately. Spring compasses are often made on a larger scale, but are not then advantageous for drawing, because they take too much time to set them by the screw. There are likewise what are called hair compasses, because they measure to a hair's breadth. They are a pair of common dividers, but the steel part of one of the legs is attached to the brass by a long spring, which constantly tends to throw the point inwards, and is counteracted by a screw passing through the brass, and tapped into the leg, so that it draws the leg close to the brass. Having opened the compasses nearly to the distance required, by turning the screw, the point is accurately adjusted to it. The only objection to this is, that the leg, depending only upon the spring, is not strong as it should be, but yields very materially when pressed into the paper, and is not therefore to be depended upon for accuracy.

Triangular compasses, (see Fig. 2,) are very useful in taking the distances of three points at once. A is the edge view of a pair of compasses, such as shewn in Fig. 5, and B a third leg, attached to them behind by a joint a, which is formed out of the pin b passing through the centre of the principal joint. These are chiefly of use to surveyors in transferring triangles: at one operation they measure one side between the point of the compasses A, and then adjust the point of the leg B to the third angle of the triangle. By bending the joint a, it will advance to or recede from both legs together; or by turning it sidewise on the centre pin b, it may be brought nearer to either of the other points at pleasure; and thus the joint a having the properties of an universal joint, the compasses will take in any triangle.

Proportional compasses, Fig. 6. These have points at each end, the centre or joint being in the middle. They are for reducing drawings in any required proportion. Thus, any distance being measured between the points A, B, by inverting the compasses, and employing the points a, b, they will measure out a distance equal to one half of the former; or the proportion may be varied at pleasure, by altering the position of the centre D. For this purpose, the limbs or legs have slits made through them, which are cut dovetailed, and have pieces of brass fitted into them; and these two pieces are united together by a steel pin, which forms the joint. It is fitted through one piece with a round shank and a conical head, and into the other with a square; beyond this it is formed to a screw, and has a nut D fitted upon it, for the purpose of binding it tight, and thus fixing the sliding pieces fast in any part of the grooves where they are set. When this nut is loose, and the compasses shut up, the slides can be moved in their grooves, by applying the finger and thumb, to set the centre in a situation for any required proportion; and for this purpose divisions are made upon the instrument, to set the slides by; and these are numbered to show the value they bear. Thus, on one edge of the front side of the instrument are divisions, entitled lines, numbered from 1 to 10; a line which is marked across the slider being brought to coincide with any of these divisions, will divide the length between the points A a and B b in such proportion, that the distance included between the points a, b will divide the distance included between the great points A, B into as many parts as the number shows. The compasses will therefore reduce any drawing in that proportion, by measuring the distances on the original by the great points, and marking them on the reduced copy by the points at the opposite end. It is evident from the Figure, that the two legs of the instrument are not in the same plane; but one lying over the other, they appear as one when they are shut up; and there is a small stud f fixed on one, which enters a notch made in the other, and this keeps the two limbs together, whilst the centre is moved, which cannot be done except when the two legs are shut up, because it is there alone that the grooves are parallel. On the opposite edge to that containing the divisions of lines is a line of divisions, entitled circles. These are numbered 1 to 20; and the index being set to any number, the points will open in the proportion of the radius of a circle to the side of an inscribed polygon of that number of sides. Thus, if it is set to No. 8, and the points A, B are opened to the radius of any circle, the opening of the opposite points will divide the circumference into eight equal parts. On the back face of the compasses are two other lines of divisions, one entitled planes, and the other solids; these are in fact lines of square and cube roots, and are rather useful in calculation than in drawing. The line of planes or squares, shows the proportion between the areas of similar plane figures. Thus, set the centre to No. 3, and measure the side of a square in the long points, the short ones will then mark out the side of a square, which will be one-third of the area of the other; the same of triangles, circles, or any other regular plane figures. The line of solids is in the same manner, to express the proportions between cubes or spheres. Thus, set the centre to No. 2, then measuring the diameter of any sphere, or the side of a cube, with the long points, the others will show the dimensions of a sphere or cube, which will have one-half the solid content of the other. The best kinds of proportional compasses are provided with an adjusting screw, clamp and screw, like that which is applied to the measuring compasses Fig. 5; and this is so adapted, that it may be either extended between the legs, to adjust the opening of the points, or it may be attached to the sliding centre to give it a delicate motion, for the purpose of
ADJUSTING it accurately to the divisions marked upon
the legs. This contrivance is very useful, when the
compasses are employed to make calculations by means
of a plain scale of equal parts, but it is not requisite for
the ordinary purposes of drawing.

Drawing compasses for describing circles, are of sev-
eral kinds; but, in general they have points, which
are changed to draw either in pencil or ink. Fig. 8,
is a pair of compasses, which are the invention of Mr
Brunel, and we think them better adapted for general
purposes than any others we have seen. The legs or
shanks consist of two tubes A, B, united by the joint at
C, the opening of which determines the distance be-
tween the points of the legs a e and b f. These legs are
not attached immediately to the tubes A, B; but, by
the intervention of joints c, d, the points can, in all situa-
tions, be set perpendicular to the paper, or nearly so,
without which the pen cannot draw a fine line, nor can
an accurate measure be taken between the points. Be-
nath the joints c, d are a second pair, formed by a steel
pin g, fixed into the legs, and fitted through the joint-
pieces c, d. These joints bend in a direction perpen-
dicular to the upper ones, and are for the purposes of
changing the drawing points by inverting the legs, each
of which has at one end a plain steel point, marked b
and e for measuring, or for a centre point; and at the
opposite ends, one has a port crayon f, and the other
is furnished with a steel pen a. This forms a complete
pair of measuring and drawing compasses, without any
loose parts, which are liable to be mislaid, and occasion
inconvenience to change them; for in these the parts
are changed instantly. Thus, in the Figure, they are
in a state to draw circles with the pen a; but, by turn-
ing the bag end round, on the joint pin g, the plain
measuring point e is brought into use for taking dis-
tances; or by bending the joints c, d, so that the points
are directed towards each other, they become well
adapted for calibrating any circular bodies. For draw-
ing circles in pencil, the leg b f must be inverted. The
joints g, are screwed up tight, so that they move ra-
ther stiffly, and are not therefore liable to alter by the
action of drawing, though they are readily turned to
change the points. The tubes A, B are double, that is, eah
contains another smaller tube fitted within it; and
the joint-pieces c, d, being attached to the internal tubes,
whilst the parts of the principal joint e are fixed to the
external tubes, the compasses can be greatly enlarged
by drawing out the tubes in the manner of telescopes.
They must of course be very accurately fitted into each
other, and have sufficient friction to preserve the situa-
tion to which they are drawn out. When drawn out to
the full extent, these compasses will describe a circle two
feet four inches diameter, or twenty inches in diameter
without extending the tubes, although the real size of
the instrument is very little more than double that of
the Figure. This great power is obtained by the legs
having joints to set them perpendicular; and the tubes
may therefore be brought into a straight line with each
other, and the compasses act as well as before. The
frames are, besides light, and nearly as strong as solid
ones; on the whole, we can recommend them as the best
instrument we have seen for general purposes, at least
for large circles.

The bow compasses must be used for smaller sized
circles than the others will conveniently draw. A very
capital pair of these is shown in Fig. 3, of nearly their
real size. They have solid shanks and joints at c, d to
place the points perpendicular. The points themselves
are moveable, being fitted into sockets, and held fast by
the screws g, g. This admits of changing either of them.
The plain point for measuring is shown at R, and the
port crayon, or pencil leg at S, and also a dotting wheel
leg at Z, Fig. 9. Its structure has been before describ-
ed. Bow pens are always provided with a handle D
at the top, which is fixed upon the joint, and is very
useful to turn the compasses round as delicately as they
require to be moved for drawing very minute circles.
A duplicate pen-leg is frequently provided for this in-
strument; and both pens being fixed at once, it will
draw double lines at any required distance asunder, a
property which is very useful to surveyors for drawing
roads in maps. By fixing the dotting leg and the pen
leg at once, the roads may be drawn with a dotted line
at one side. Some artists prefer having two sepa-
rate pair of bow compasses; one for a pen, and another
for the pencil; they do not therefore require the socket
joints g, g, which, for very nice purposes, are rather ob-
jectionable; for unless the sockets are extremely well
fitted, the points will not meet sufficiently near to draw
the smallest circles; still a pair of these, when in good
order, may be made to describe circles of only one
thirtieth of an inch in diameter.

Pocket compasses of the best kind are shown in Fig.
7. The shanks AB are made hollow for the reception
of the upper part of the legs, which separate at the
joints e, f. The legs have joints c, d to set them perpen-
dicular. One of the legs is shown detached to explain
its mode of operation. It will be seen that the plain
point at one end, and the port crayon at the other. It
has two parts at l and m, each formed to fit into the
sockets or end of the tube forming the shank of the compasses. This admits of either point being brought into use or the other end of the leg may
be introduced into the hollow of the shank, and then
the opposite leg may be in use. The parts l, m must
be accurately fitted into the sockets, and must be at
equal distances from the points, otherwise the points
will not be of corresponding length when changed. The
leg q with the steel pen has likewise a plain point at the
other end, which is concealed within the hollow of the
shank A. The fitting of the parts l and m consist of a
round pin accurately fitted into the sockets at the ends
of the tubes, and with a small steel feather or fillet fix-
ed, projecting from one side of the pin, and received into
a corresponding notch in the side of the tube. The
great convenience of these compasses is their portabil-
ity, for the points or legs being put into a sheath or
thimble, they can be carried in the pocket without
any other case, and contain a very good set of instru-
ments in themselves, which an artist may at all times
carry about with him. The only objection to them is,
that if they are much used, the sockets wear, and the
legs will then have a shake or looseness, which must of
course be destructive of all accuracy, in either drawing
circles or measuring distances; neither can the points
be changed so readily as those of Mr Brunel’s, Fig. 8,
which are merely inverted.

We have now described all the jointed compasses
which we think particularly worthy of notice; for
through a number of different constructions beside those
are in constant use among artists, they are not so per-
fected as the above. Compasses require exceeding good
workmanship, particularly in the joints. The parts of
these should be always composed of two different met-
als, and are best made by soldering or brazing two
thin plates of steel to one leg, and fitting them into cor-
responding openings or clefts cut in the metal com-
posing the other leg, which is generally brass or silver.
The centre pin should be steel, and accurately fitted

---

Mr Brunel’s compasses.

Plate CXXXVII.

Fig. 8.

Pocket compasses.

Fig. 7.
to the holes made through all the parts of the joint. At one end it has a head of brass or silver riveted fast upon it, and on the other end a similar head is screwed, which is therefore a nut, and being turned by a screw driver, binds the joint tight to produce any degree of friction or stiffness required; for the object in making a joint is to give it a great degree of friction, and at the same time to be perfectly equable and regular in all parts. For this reason the joints should always be double, that is, have two pieces of steel in the joints, by which means there are four separate surfaces in contact to produce friction, and are therefore less liable to wear than if there were only two surfaces, which is the case when only one piece of steel is used. The joints of all compass instruments not being so well fitted in the circular part have leaves or projecting parts on these steel pieces, which enter notches at the upper part of the opposite leg when the compasses are shut, but these leaves draw out from the notches as the compasses are opened. This is not a good method, because the friction is then unequal at the different degrees of opening, and such compasses are liable to jump suddenly when shut up or opened by the gradual pressure of the fingers. All the instruments in Plate CXXXVII. are made fit in the circular part of the joint only, and this should be made large enough to give as much steadiness as the instruments require. The steel legs of compasses should be of cast steel, hardened and well tempered at the points, so that they will preserve a sharp point, without being so soft as to turn up even when used on brass or copper, or so hard as to be brittle. The upper part of the steel above the points should be of a spring temper, and then they cannot become bent by any accident, so as to prevent the points meeting each other precisely as they should do to measure minute distances.

When the points by gradual wear become dull, they should be repaired by sharpening on an oil stone or hone. The insides of the points should first be rubbed quite flat upon it, till on shutting them together the two points meet as if they were one; they are then to be rubbed on the different sides till both are brought to fine points, which should be tried on paper, till they make very delicate punctures. The strength of the legs should be such, that when the pressure of the fingers is applied to the compasses to open or close them, they will not bend or spring sensibly by the force which is requisite to open or close the joint; if this is found to be the case, the joint must be relaxed by turning the nut of the screw. No accurate measure can be taken in compasses which are so tight in the joint as to cause the legs to spring in opening or shutting, because when the points are brought by the pressure of the fingers to the required opening, they alter their distance the instant the pressure of the fingers is relieved as much as they spring, which, in some compasses, is a very considerable quantity.

For measuring very long distances, the beam compasses alone can be used, and also for drawing portions of large circles. They are usually made with a wooden beam, as shewn in Fig. 13, and two brass sliders A, B fitted upon it. These have screws through the upper part of them, by which they can be fixed fast upon any part of the bar; and in the lower part are sockets for the reception of the different points c, b. These consist of two plain steel points, a steel pen, and a port crayon. A screw d is mounted in a socket or frame, screwed to the end of the slider B, and this screw is tapped into a piece of brass which is fixed at the end of the wooden beam; therefore by turning the screw round by its head d, it acts upon the slider B, and slowly ad-

vances it upon the beam to the exact distance required. In the best instruments, the head of the screw has a circle fixed upon it which is divided, and thus the quantity that the point is moved by the screw is ascertained with great precision. The same compasses have generally several beams of different lengths, as it is inconvenient to have a beam of much greater length than the distance between the points.

When arches of circles of very great radius are to be drawn, the beam compasses are not the best instrument; even when they are extended to five feet in length, the beams are very liable to bend by their own weight, and thus throw the points farther from each other. They must be used to handle them delicately and support the beam in the middle.

Many artists require very large circles, particularly those who project maps of extensive countries. To these we can recommend the instrument Fig. 14. This consists of two rulers A, B, united by a joint at C, which admits of placing the two at any required angle with each other. They have each a circular part behind the centre, and in the upper one is cut a curved groove for the reception of a screw d, which screws into the lower one; therefore by screwing this tight, the two are immovable fastened together at any angle at which they may be set. The centre pin of the joint C is perforated, forming a tube to admit a cylindrical pen, on the lower end of which the drawing point or pin is fixed, and in such a position that its point is in the intersection of the edges of the two rulers A, B. When this instrument is used, two weights E, F are laid upon the table, and they have sharp edges, against which the rulers are applied, as in the Figure; and when it is slid along against them, the centre point C will describe an arch of a circle. The edges of the weights E, F are only necessary to represent a stationary support against which the rulers can be applied; and therefore two pins or needles stuck in the table would have the same effect, and indeed are often used. For the same purpose, each of the weights must have three small pins in the underside of it, which are pressed into the table to hold it fast. By altering the angle of the two rulers, the instrument will draw a segment of a circle of any required radius; and the mode of setting it is extremely simple: First, mark on the paper two points, which are to be the extreme limits of the arch to be drawn; then, by drawing the chord and versed sine, an intermediate point upon the curve between these two may be found; now fix two pins in at the extreme points, or place the weights E, F so that their edges match these points, and apply the instrument to them; now loosen the screw d, and open or close the angle of the rulers A, B, till the centre point C exactly falls upon the intermediate point in the curve. Here fasten them by the screw, and the instrument is ready to draw the curve by sliding it gradually against the pins, whilst the pen in the centre traces upon the paper.

Fig. 21 is an instrument for dividing circles into Farey's divisions, which was invented by Mr Farey. It consists of a light brass or silver circle AA, having a cross bar a with a centre screw fixed in it; and the point of this screw is made very delicate, that it may enter the paper without making an unseemly puncture. Upon this centre the circle revolves, and its circumference has several circles upon it, which are divided in an engine, and holes drilled through the plate at every division, in the same manner as the divided plates of the engines used by watch-makers for cutting cog-
wheels. There are 6, 7, 8, or 9 of these circles, each containing a different number of holes or divisions; thus the outer one may be 360, then 100, 96, 90, 84, 72, or it may have any other numbers at pleasure, though these will be found sufficient for general purposes. These divisions are transferred to the paper at any radius, by means of an index c d. This is a piece of steel attached to an axis e f by means of a thumb screw g, which passes through a slit in the index, and screws into the axis beneath, so as to bind the index fast, and attach it firmly to the axis e f; but when the screw is loose, the index will slide, so as to bring the screw c nearer or farther from the centre, to adjust it to the radius of the circle it is intended to divide; for it is the point of this screw which pricks into the paper to mark the divisions, and it is for this reason made very sharp. The axis c f is supported upon the points of two centre screws, fixed through holes projecting from the central bar a; and there is a small spiral spring, consisting of a slender piece of music wire twisted round the axis, being secured to it at one end by passing through a hole in the axis, and the other end is turned up to rest on the central bar a; by this means it constantly tends to throw the prick ing point of the index upwards from the paper. The divisions of the circle A are united by a steel point, at the end of a small detent l m, which moves on a centre, and has a spring under it at the end m, to throw the opposite end down, and cause its point to enter the holes as they pass in succession beneath it, when the circle turns round. The centre of the detent is supported in a piece of metal n, which has three very small points in the under side of it, that it may fix itself firmly upon the paper, when held down by the pressure of one finger placed upon it. The manner of using the instrument is this: Place its centre point in the prick which has been previously made in the paper, as the centre of the circle intended to be divided, and which may, if thought proper, be drawn in pencil; then loosen the screw g, and slide out the index till its point c reaches the circle, and here fasten it to the axis by the thumb screw; now take the detent, and choosing the circle containing the number intended to be divided, put its point into one of the divisions of that circle, and placing the piece n at any convenient part of the circle, press its three points into the paper to keep it steady, and hold it down by placing the second finger of the left hand upon it: The thumb of the same hand is to be placed on the rim of the circle, near the point A, for the purpose of moving the circle round upon its centre, and the fore finger is reserved to press down the tail m of the detent, and thus raise its point out of the divisions. Having with the thumb moved the circle round, till, by the point of the detent dropping into one of the divisions, it becomes fast, and will turn no farther, you press with the fore finger of the right hand upon the head of the screw c, and cause its point to prick into the paper, making the first division; then suffer the spiral spring to lift up the index c, and take its point out of the paper, and at the same time press down the tail m of the detent to relieve the circle from its points, and, with the thumb, move the circle till the point of the detent falling into another hole stops it at the second division; here prick the pin c into the paper, then lift the detent, and move the circle another division; mark again, and so on, till the whole numbers are divided, which may be done very quickly, and with as great accuracy as it is possible to obtain upon paper. The stud which supports the centre of the detent, turns round in a socket in the piece n, by which means it can be turned to reach any one of the circles of divisions at pleasure. If a circle is to be divided into one-half, one-third, or one-fourth, of any of the numbers divided on the Plate, it can be done by suffering the circle to move 1, 2, 3, or 4, divisions every time, before the prick is made, instead of once. The numbers divided on the circle may be doubled thus: Having divided one circle as described, subdivide one of the divisions; then loosen the screw g, and move the index sidewise the quantity of half a division, till on trial the point will exactly enter the subdivision at the time when the point of the index is holding the circle by one of its divisions; now fasten the screw, and proceed to divide the circle over again; then the division made the second time will fall exactly between those first made, and thus fill up the circle with double the number first set out. Instruments on this plan may be made to any size less than eight inches diameter.

Fig. 20. represents another instrument by Mr. Farey, which has the power of drawing lines, as well as marking points. The circle of this is exactly the same as the former, except that the radial bar has an arm behind it. The instrument is provided with a similar detent to count the divisions, but instead of the index for pricking, a brass frame a b c is fixed upon it by a screw a. It supports the ends of a steel wire a b, upon which is fitted a sliding socket d, adapted for receiving the leg of a pair of compasses l, which are of the same structure as Fig. 3: the leg fits fast in the socket, which may therefore be considered as one piece with the leg. The opposite leg of the compasses then stands in a proper direction to draw lines on the paper, when motion is given to it, by sliding the socket upon the wire. This must be very accurately fitted, to be without any shake, and it will then draw a straight line parallel to the wire. The length of this is limited to what is required by adjustable stops, 1 and 2, which fit upon the wire, and by means of a small screw can be fastened at any part: one of these stop the motion of the socket each way. It is plain that, by opening the compasses out, the lines may be drawn at any required distance from the centre; or, by twisting them round on the joints, which fix in the legs, they may be drawn at any part of the area of the circle, and their length is determined by the stops.

Fig. 22. is a very convenient protractor, combined with a dividing instrument, which was invented by Alexander Jaffray, Esq. It is a semicircle AA graduated on the circumference with degrees; and within this are several portions of circles divided into different numbers, and drilled through the plate like the former; the centre screw has a point to enter the paper, and it is also the centre for an index or limb CD. This has a vernier at the extremity C to apply to the graduated arch AA, and within it carries a detent which moves on two centre screws as an axis, and has a point to enter the divisions of the several circles. This point is fitted through a groove made in the detent, but can be fastened at any part of the length of the groove by a thumb screw, and in this manner it is set to any of the different rows of divisions. The tail of the detent is brought very near to the centre, to be convenient for the application of the finger upon it. The drawing of the lines, or marks, is performed by means of a ruler B, which is attached to the opposite end of the limb, and traverses over the paper, having a thin edge which points to the centre, as does likewise the edge e of the semicircle, when it is used as a protractor, the angle
made between these two edges B and e is measured by the divided arch and vernier; but when it is used for dividing, the point of the detent is set to the required circle, and the semicircle held down fast upon the paper, whilst a mark is made by the edge of the ruler, as shewn in the Figure. The tail of the detent is then pressed to relieve the limb from the circle, and it is moved another division, and here another mark is made by the rules, and so on, till as many divisions as the semicircle contains are made. Having arrived at the last, the ruler B is to be held fast, by pressing it down upon the paper, and at the same time holding down the tail of the detent. To release the circle from it, the semicircle may be turned round on the centre till the detent come to the commencement, and from this set out again to complete the dividing of the circle, holding the semicircle fast, and turning the ruler round a division at a time, as before described.

This instrument is scarcely so convenient to use as the former, on account of the interruption in the middle of the work to change the position of the semicircle; but it has one great advantage over them, viz., that it can be extended to circles of larger radius than the instrument itself, because the ruler B may be extended to any length required, whereas the others cannot divide circles larger than the area of the opening within them.

The pentagraph is an extremely useful instrument to copy drawings, which it will do either on a reduced or enlarged scale, or on the same size, at pleasure. For copying maps or drawings, where almost all the lines are irregularly curved, it is the most valuable, because there is no other direct method of obtaining copies of such lines. The principle of this instrument may be easily explained by Fig. 7. AB and BC are two thin brass rulers, united by a joint at B. DF and EF two shorter rulers, united at F, and attached to the long bars, by joints D and E. The proportions of the rulers are not important, except that they must form a parallelogram, DF being = BE, and DB = FE; therefore in all positions EF will be parallel to AB. The instrument opens and shuts freely upon its axes, and one of these is a small castor, or wheel, to support the weight of the instrument, as it traverses horizontally upon the table. A, G, and C, are three points upon the rules, where tubes are fixed to receive the drawing points. These three must be in a right line, as shown by the dotted line, and so situated that the distance CG will divide the distance CA in the proportion in which it is required to copy or reduce the drawing at A, upon the paper at G, by means of a pencil or point crayon, inserted into the tube G; at A, a blunt tracing point is fitted into the tube; and the third point is kept stationary, by means of a circular leaden weight placed upon the table, and provided with small pins in the underside, to prevent it from moving. The point C, therefore, becomes the fulcrum or centre on which the whole instrument moves; and with this motion, combined with that produced by extending and contracting the instrument, the tracer A may be passed along all the lines of the drawing, however irregular, and will communicate such a motion to the pencil at G, as to copy it exactly in the proportion of the distances CG to CA.

It has been before mentioned, that the three points must be situated in a right line; and it follows from the arrangement of the rulers, that they will, in all the motions of the instrument, continue in a line with each other, and will divide its length in the same proportion in which they were first set upon the rulers.

The instrument acts to copy and reduce on the principle of the lever; considering the imaginary line AGC as an inflexible lever, the fulcrum may be placed in either of the points G or C, and in the other the pencil is to be put.

The point A is always used for the tracer, which is applied to the original map or drawing, and the proportion in which the instrument will reduce is thus: As the distance between the tracer and the fulcrum is to the distance between the pencil and the fulcrum, so will the size of the drawing traced over be to the size of the copy made by the pencil. Example. Put the sliders G and C at such parts of their respective rulers as will cause the distance CG (when they are in a straight line) to be only half as much as AC; then if the fulcrum is placed at G, the pencil at C, and the tracer at A, it will reduce to one-third, because AG is three times as great as CG. On the other hand, put the fulcrum at G, and the pencil at C, and it will reduce only one half; because in this instance AG, from the tracer to the fulcrum, is twice as much as GC, from the pencil to the fulcrum. It must be remembered, that when the fulcrum is placed between the tracer and the pencil, the copy will be inverted with respect to the original; but in the former case, they will be parallel to each other upon the table, as shewn in the Figure. The pencil and tracer should be lightly oiled before they are used, to make them move freely in their tubes.

The tubes are fitted upon the rulers by means of sliders, (see Fig. 8,) which have a screw a, to fasten them at any point. The tube b has the port crayon d accurately fitted into it; and this has a cup or box on the top, by which it is loaded with shot or other small weights, till a sufficient pressure is obtained to make it draw a clear line. That part of the tube b which is beneath the ruler, is made of a proper size, to fit into a socket, which is formed in the lead weight, Fig. 9, at d, and it is this which forms the centre or fulcrum. The socket is very near the edge of the weight, that it may be so placed as to admit the motion of the castor, which is under the joint E, Fig. 7, when the socket is brought up near to that joint, for reducing very small. The accurate fitting of the points is very material for copying correctly; and the instrument must be used upon a very flat table, or the points will, by the friction of the instrument, be thrown out of the perpendicular. To avoid this danger as much as possible, all the joints are made with short axes, as shewn in Fig. 10, where f is the end of one of the rulers, having a short steel axis screwed to it. The pivot at the lower end of this is received into a tube g, which is fixed to the other ruler; and the upper pivot is sustained by a cock or bridge k, screwed to the same ruler. The tube g also receives the spindle h of the castor, or wheel, on which the instrument travels. This has at the lower end a piece of brass, into which the wheel is fitted, so as to turn upon its own centre; and by the spindle h turning within its socket, the plane of the wheel always accommodates itself to the direction of the instrument's motion. The spindle h is retained in its place by the point of a small screw entering a notch made round in the spindle. The rulers of the pentagraph are marked at C and G, with divisions by which the sliders are set; and these are figured, to shew the proportions in which the instrument will reduce when they are so placed.

Fig. 6 is an instrument, invented by Mr. Farey, for the purpose of drawing lines converging to an inaccessible centre. This is extremely useful to those who draw buildings, &c. in perspective, when the points to
which the lines should converge will often fall at a distance of 12 and 15 feet from the picture, so as to render it impracticable to use rulers; and there is, except this instrument and another recently invented, no other method. It consists of three rulers A, B, and D, which are united by a common centre screw; and have a thumb-screw d, which fixes them fast at any angle where they may be placed. E, F are two fixed weights, against the edges of which the rulers AB are applied, when the instrument is used; or pins may be fixed in the table, to answer the same end. By sliding the instrument against these stationary points, as shewn in the Figure, the ruler D will draw lines as shewn dotted, which are all convergent to a common centre, the distance of which will depend upon the angle of the rulers A, B, and the situation of the points E, F. The edge of the ruler D must in all cases be made to bisect the angle of the other two. The manner of setting the instrument is this: Having given the two extreme lines r, s (dotted), which converge to the intended point, we suppose it is required to draw a number of others to the same point. The pins or weights E, F must be set upon these lines, but situated equally distant from the centre point. To find their situation, place a pair of compasses with one point between the two lines r, s, so situated, that when a circle is described by the other point, the two lines will be tangents to it. From this point, as n, with a greater opening of the compasses, mark off two points, as at E, F, upon the lines, and these will be equidistant from the centre; and here place the weights, or fix the pins. Now apply the instrument to them, with the clamp screw d loose, and slide the rulers against the pins, till the ruler D comes to one of the lines r or s; and here place the rulers on their centre joints, till the edge of D exactly corresponds with the line, when the other rulers are kept in contact with the fixed points. Now remove the instrument to the other of the two lines, and adjust it in the same manner that the edge of D may correspond with it. The clamp screw being fastened, fixes the rulers as they are adjusted; and then, on sliding the two A, B, against the pins, the edge of the third, D, will in all positions tend to the same centre point as r, s, &c. The angle C, in which the rulers A, B meet, will in this motion describe a segment of a circle, as shewn by the dotted lines; and the centre to which the lines tend will be found in the opposite circumference of that circle, by bisecting the distance EF upon the dotted arch, and from this point drawing a line through the centre of the circle till it cuts the opposite circumference, and to this point the lines will converge.

If the instrument is required to have a greater range than between r and s, other pins must be fixed for it to act against, taking care that they are at the same distance from E or F as these are from each other. Their proper situation will be determined by the rulers A, B themselves, thus sliding the rulers against the pins till the angle C comes to one of the points E or F. The new point must be fixed in contact with the edge of the ruler, which is unsupported, and at the same distance as is between E and F.

The construction of the instrument will be apparent from an inspection of the Figures. The two rulers A, B have circular parts behind the centre, which apply one upon the other; and a projecting part b from the ruler D lies over both, the centre passing through all three. An arched groove is cut through both the circular parts, to admit the screw d, which also passes through b, and fastens them all three together, by screwing into a nut, which is fitted into the arched groove of the lower one. The ruler D is made of wood or ivory, as shewn separately in Fig. 6, and screwed to the under side of b, so that it comes into the same plane with AB. The instrument will draw parallel lines when AB are set in a straight line; and if the circular part is graduated, it will make a good protractor.

Fig. 6 is an extra ruler, to be applied in lieu of D. When the instrument is required to draw lines to a centre on the opposite side, it is merely reversed to the other, having the hole in L, which is for the centre, in the line of the opposite edge, towards the left hand side, and the other towards the right hand. This instrument has been lately rewarded by the Society of Arts, who have also rewarded Mr. Peter Nicholson, for the invention of an instrument for the same purpose, which he calls a centralised. It is on a new and very ingenious principle. See the Transactions of the Society of Arts, vol. xxxii.

Ellipses are curves so frequently required by all artists who draw in perspective, that instruments for drawing them to any size or proportion, are almost indispensable to produce correct representations of circular objects. The trammel, or elliptic compasses, Figs. 1 and 11, is the only method which is in general use. It consists of a brass cross, AA, BB, having two dovetailed grooves crossing each other at right angles. In these grooves, sliders are fitted to move freely, and without looseness. The sliders are perforated with holes for the admission of small pins, which project downwards from the sockets CD of a small brass compass, at the extremity of which a tube E is fixed, and in this a drawing pen is received. The cross is supported upon points, which act as legs, and at the same time point out the direction of the two diameters of the ellipses, which the pen will trace when the beam is turned round. In doing this, the sliders being united together by the beam, compel each other to advance and retreat in their respective grooves; and thus, by a constant alteration of the centre, produces an ellipse, instead of the circle, which would be drawn if the centre was immovable.

The rule for setting the trammel is to make ED equal to half the conjugate diameter of the intended ellipse, and EC equal to half the transverse diameter; therefore the distance DC will be equal to the difference of the two semi-diameters. Fig. 11, will explain this more clearly. This instrument is very defective, because it will not draw narrow ellipses, nor small ones, without interruption to the curve, by the arms of the cross, as shewn in Fig. 11. For very small ones, it cannot be used at all; neither will it draw ellipses which approach very near to circles, because the sliders cannot be brought sufficiently near together. Another inconvenience is, that when the cross is once placed, it must remain, and cannot be adjusted till it come to the exact position required upon the paper. For these reasons the instrument is not applicable to perspective drawings, as the greater portion of these ellipses which occur could not be drawn by it.

Fig. 2 is an ellipsoidograph invented by Mr. Farey, which is so general in all its applications, as to draw any ellipses whatever within the size of the instrument, and is readily adjusted. It consists of two circles A, B...
united together with screws, with any required degree of eccentricity from each other. These revolve between four rulers, DE and FG, firmly screwed together to form a frame: but they are in two different planes, as shown by Fig. 3; so that the upper circle is included between FG, and the lower between DE. Both circles are accurately fitted, with liberty to slide freely between their respective rulers, but have no other motions; therefore the centres of the two circles always move in right lines, which are parallel to the rulers, and at right angles to each other, as shewn by the dotted lines ED and FG. The curve is traced by the pen of a pair of compasses MH, situated as shewn in Fig. 5, the leg being stuck fast into a socket H, which moves on a centre or axis; and the pen M of the compasses is capable of being lifted up at pleasure, that it may not mark upon the paper: and when in use, this centre permits the pen to follow the surface of the paper, and always press upon it with a proper force to draw neatly. The circles of the instrument are turned round by means of six small handles f fixed in the circumference of the upper circle, and to any opposite two of these the finger and thumb of the right hand is applied, whilst the frame of the instrument is held firmly down upon the paper by the finger and thumb of the left hand pressing upon the two nuts O, N; then turning the circles round in their frame, the pen will draw the ellipsis as in the Figure. The principle on which this instrument operates, is the same as the trammel. To shew this, Fig. 11. represents the same ellipsis as in Fig. 2, with a trammel properly set for describing it in the manner before explained. The alteration consists in extending the diameters of the pins which act in the grooves, till they become the large circles, AB, Fig. 2; and then the rulers DE and FG represent the sides of the grooves in which the pins move. The point of the pin of the compasses M now represents the point E, Fig. 11. and draws the curve in the same manner; but by these alterations, the instrument becomes general in its application; for the point M has the power of extending any distance from the centre, and any required eccentricity can be given to the circles, still preserving the advantage that the point M can be actually brought to coincide with one of the points D or C, Fig. 11. when of course it will draw a straight line, and if brought to agree with both of them, it will describe only a point; therefore this instrument will describe all possible varieties of ellipses within the limits of its radius, either with respect to size or the proportion of its diameters. To explain the adjustment of the instrument, we must return to Fig. 2, which shews that the circles have no central bar, but instead of it have two bars a, a parallel to each other, and at some distance from the centre, leaving an open space between them, in which the drawing pen or tracing point is situated. There are also crooked arms b, b proceeding from the bars a, a to the circular rim, to give them sufficient strength; and these being all the bars across the circle, it leaves them sufficiently open to see the curve as it is traced beneath by the drawing pens. The circles are united by screws, which keep them together, but at the same time allow them to slide one upon the other, in the manner of the Figure, by means of a pinion K, the centre pin of which is fixed on one of the arms of the lower circle, and acts upon a rack d, screwed to the upper circle, so that it separates the two when turned round by its head K. But the circles are fitted together so tight by the screws, that they will not separate from each other, except by the power of the pinion, and may, in the motion of the instrument, be considered as firmly united together, though capable of having any degree of eccentricity given to them by means of the pinion K. The other adjustment, viz. that which removes the drawing point to any required distance from the centre, is produced by a pinion L on the opposite side, which gives motion to a small carriage or frame g. This carriage is fitted into the space between the bars a, a, and slides freely from one end of the opening to the other by means of a rack h screwed on one side of it to act in the teeth of the pinion L, which turns on a centre pin fixed in the upper circle BB.

The frame g has the brass socket H within it fixed on a centre pin extended across the frame. There is a hole in the socket for the reception of the leg of the drawing compasses H, which stand, as in Fig. 3, when in use, the pen tracing the curve upon the paper, by the weight of the compasses bearing upon it. The manner of fitting the frame g into the bars of the circle is shewn in Fig. 4; and also the socket H moving on its centre pin, the rack d and the pinion K, which are for the purpose of separating the circles, and the other rack and pinion L, h for moving along the frame g between the bars. The frame g is so fitted that it continues at the same point with respect to the upper circle B, when the two circles are separated from each other by the motion of the pinion K. We have now shewn that the circles can be set with any required degree of eccentricity, and in this state are capable of revolving in the frame; and also that the tracing point or pen can be removed to any required distance from the centre of the upper circle B. We shall now proceed to point out the extreme cases of the instrument's action. Suppose the two circles set by the pinion K, exactly concentric with each other, and the pinion L turned till the end of the frame g comes in contact with the rim of the circle, then the point of the pen M will come exactly in the centre of both circles, which being turned round in the frame by their handles, the pen will only mark a small point on the paper, which will be the centre of any curve the instrument may be afterwards made to describe. By turning the pinion L, the point of the pen may be removed to any distance from the centre within the radius of the instrument, and it will when turned round describe a circle which may be made of any radius from the smallest point to the size of the circles. This is the simplest case of the instrument, and may be considered as an ellipsis when the difference of its diameters is infinitely small. When the circles are rendered eccentric, it draws an ellipsis, the breadth of which will be determined by turning the pinion L; and by the other K, the difference between its breadth and length is regulated. Suppose K turned, to render the circles concentric, without moving the other pinion, the pen therefore remains in the centre of the upper circle. In this case, the pen will describe a straight line, equal in length to twice the eccentricity of the circles. This is evident, because the circumference of the upper circle BB, moving between the straight edges F and G, its centre must describe a line parallel to them. This case may be considered as an ellipsis without breadth; for if the pen is set the smallest quantity out of the centre of the upper circle, it will describe a very narrow ellipsis, and by setting it at different distances from the centre, any required proportion of ellipses may be described.

When the instrument is held down to draw, it is kept steady by two sharp points, fixed in the ruler P, and penetrating the paper. This ruler is united to the frame by screws, on which the nuts N, O are screwed. The screws are fitted into grooves in the ruler P, in which
they slide; and they also pass through grooves in the ends of the bars of the frame. By this means, when the instrument is placed on the paper, it can be moved to adjust it to the exact position, where the ellipse is to be drawn, without disturbing the ruler P. To remove the transverse diameter of the ellipse, (the conjugate remaining the same,) the whole frame is moved by the screws sliding in the grooves of P; but to move it in an opposite direction, viz. to adjust the position of the ellipse endwise, the nuts must be loosened, and then the screws will slide in the grooves at the ends of the bars FG. When the nuts are screwed fast, this motion is prevented, though the screws will still slide in the grooves of P.

The properties of this instrument will be rendered most evident, by some examples of the manner of using it. All that is required, as data for describing any ellipse, or any number within or near each other, is, to sketch them in pencil on the paper, and mark, by the compasses, the four points upon each curve where its two diameters intersect it. Place the instrument upon the paper in such a position, that, by the estimation of the eye, the centre of the four rulers seems to coincide with the centre of the intended ellipse, the two upper rulers being parallel to the longest diameter of the curve. Here fix the instrument by pressing the two pins of the ruler P into the frame, and hold it fast, by placing the thumb and fore finger of the left hand upon the nuts NO, leaving the other hand at liberty to turn the circles about by applying the finger and thumb to any opposite two of the small handles f.

Now, by turning the pinion L, remove the drawing pen to one of the marks made for the extent of the shortest diameter of the ellipse; then turn the circles one half round by the handles, and examine if the point of the pen comes exactly to the opposite mark, for the other end of the shortest diameter, if it does not adjust the error one half by moving the pen with the pinion L, and the other half by moving the whole frame on the paper, then by returning the circles back again, the accuracy of the adjustment will be ascertained; for if it meets the former mark, it proves that the circles are in the right centre, and that the compasses are set to the proper diameter for the conjugate axis. Now turn the pen towards the length of the ellipse; and, without altering the compasses or pinion L, slide the circles one upon another by the pinion K, till the point of the pen arrives at the mark made for the length of the ellipse; turn the circles half round to the opposite end, and if they match the mark made there, the adjustment is correct; if not, one half of the error must be corrected, by moving the circles by their pinion K, and the other by moving the whole frame sideways on the paper. To do this, the nuts X, O must be made loose, and then the frame will be at liberty to move. The adjustments being made in this manner, the pen may be suffered to rest upon the paper, and trace round the curve. The Society of Arts rewarded the inventor of this instrument with their gold medal, and have published a description of it in their 21st volume of Transactions; and also a plate of specimens of the curve drawn upon the copperplate by an instrument of the same kind. This instrument, however, has an additional apparatus for dividing the ellipses, when drawn, into any required number of divisions, which shall be the representation of a divided circle, either in true perspective, which artists call the scenographic projection, where the divisions on that side which is nearest to the eye will be larger than those on the most distant, or it will divide in the or-thographic projection, where the eye being supposed at an infinite distance, the divisions on the distant and adjacent sides of the ellipse are equal, and only that difference made in the divisions which is produced from each being viewed with a different degree of obliquity. Numerous specimens of the application of this ellip-tograph may be seen in the Plates of our Work, particu-larly in Block Machinery, and Coining Machines.

Fig. 11 is an instrument, called the geometrical pen, Geometrical which will describe many different curves, though most of them are species of epicycloids. A, B, C are three legs, which form the frame, and support a central axis, ccxxviii. a; upon this a centre, a tube b is fitted to revolve when the finger is applied to the milled circle r; the tube carries an arm d, which supports the wheels e and f, and therefore the centres of these describe circles round the principal axes: g is a cog wheel, firmly fixed upon the lower end of the axis a, and is therefore stationary; but by the revolution of other wheels round it, they have a rotation given to them upon their own axes. The arbor n of the wheel f, has an arm h attached to it, and this at the extremity carries the tube which receives the drawing point k to trace upon the paper. The pencil has therefore a motion round its arbor n, and at the same time this centre is revolving, with a slower motion, round the central axis a. By proportioning the velocities of the movements, a number of curious curves will be found, some similar to that which the moon describes by the compound motion of revolving round the earth at the same time that she is moving in her orbit round the sun. It makes looped figures, resembling stars or flowers, and of any required number of loops or leaves; but as it is impossible to describe these without giving plates of them as examples, we shall not attempt it, but refer our readers to an examination of the machine, or to Adam's Graphical Essays, in which a great number of these figures are given. He ascribes the invention of the instrument to John Baptist Suardi, who enumerates 1273 curves which may be drawn by it. To accom-plish these, many different sized wheels are used, and the revolving arms must be placed at various distances. For this purpose, the wheel g is fitted to the axis, so that it can readily be removed, and another substituted in its place; the wheel e is fitted upon a pin, which slides in a groove cut through the arm d, as shown in Fig. 12 and can be fixed at any part of it by a clamp nut, so as to suit the radius of the other wheels. In like manner, the tube which receives the axis n is fitted on a box which slides upon the arm d, to adjust the distance of the axis n from the central axis; the wheel f, which is fixed upon it, can be readily changed to apply one of a different size, and, lastly, the arm k of the pencil is fitted in a mortise the lower end of the axis n, and is obtained by a screw, by which means the pencil can be removed to any required dis-tance from the axis; and it is by the different propor-tions of these wheels, and the lengths of the arms, that all the above-mentioned varieties of curves can be produced.

Instruments for drawing in perspective are very nu-
merous; but the Camera Lucida, invented by Dr Wo-
Instru-laston, deservedly takes the preference: (See that ar-ticle.) A new and ingenious instrument, invented by Mr Turrell, has been lately rewarded by the Society of Arts, and promises to be very useful to artists. We have not been able to obtain a description of it, as the So-ciety has not yet published their account of it, but we shall probably have this in our power under the article Perspective. (J. P.)
DREAMS must be so familiar to our readers, that it seems superfluous to define them. They are among the most curious phenomena of the human mind; and at the same time, the most difficult to be satisfactorily explained. The interest which they have excited in all ages, both among the vulgar and ignorant, and among philosophers, has been very great and general. The earliest authentic records of history inform us, that dreams were regarded as supernatural or prophetic; and this idea has descended, at least among the common people, even to our own times. The Greeks and Romans paid particular attention to them. They divided them into five sorts: the first distinction, as given by Macrobius, refers to what is properly called a dream, *somnum,* this he considers as a figurative and mysterious representation, which requires to be interpreted. The second species relates to what is termed vision, *visio,* which was, when any one saw that which afterwards came to pass in the same manner that it was foreseen. The third sort, the ancients conceived to be oracular, *oracleum,* this they described as taking place, when in sleep any venerable person, or deity, denounced what was or was not to happen, or what should be done or avoided. All these sorts of dreams were supposed to arise under the influence of inspiration; and in order to procure them, it was usual to lie down to sleep in the temple of some deity. The fourth sort was the *insomnium,* *evocius,* this Macrobius represents as proceeding from the solitude of an oppressed mind, body, or fortune, which having harassed us when awake, affects us when asleep; and respecting this sort, the ideas of the ancients seem to have been tolerably just and rational; for, not regarding them as arising from the influence of inspiration, they endeavoured to trace them to natural causes. These dreams, however, they regarded as deceitful and vain. The last sort is called *phantasm* by Macrobius, and *visio* by Cicero. According to these authors, it took place between waking and sleeping; as in the first clouds of sleep, when the person who begins to doze, thinking himself awake, imagines that he sees forms differing in shape and magnitude from natural objects, rushing upon him, and wandering about. Under this class, the ancients placed the *epithalides,* or *night-mare.* Some other of the ancient writers on dreams divided them only into two classes, plain and allegorical; the former exhibiting things in their proper form, *epiesiugia*; the latter, such as intimated circumstances under similitudes. Besides Macrobius and Cicero, several others of the ancients wrote on the subject of dreams, either directly and fully, or incidentally, as Plutarch, Zeno, Cleanthes, Chrysippus, Babyloniurn, Diogenes, Antipater, Poseidonius, Aristotle, &c. The exposition of dreams was reduced by them to scientific principles, and practised by men who engaged in it as a profession. Some writers distinguish between *dreamers of dreams,* *onmatheia,* and *expositions of dreams,* *onmatheoi.* It appears from a passage in Plutarch's life of Aristides, that certain tables were used for the interpretation of dreams; he speaks of Lysimachus, a grandson of Aristides, who, sitting near the temple of Bacchus, gained his livelihood by it. But the most laborious and solemn trifier on this subject among the ancients was Artemidorus, who lived in the reign of Antoninus Pius. His whole life seems to have been spent in going about collecting dreams. The fruits of his labour are still extant, in a large work entitled *Ostroecritus.* A person still more singularly devoted to the study of this sub-
ject was Jonianus Magnus, a Neapolitan, who lived in the 15th century, and was the instructor of the celebrated Sanagorius. Magnus is deservedly known to the classical scholar, as having essentially contributed to the revival of the Latin language; but in his own time he was much more celebrated for his skill in the interpretation of dreams. Besides Sanagorius, Alexander ab Alexandro was one of his disciples; and he informs us, that every morning the house of Magnus was crowded with persons of the highest rank, who came to tell him their dreams, in order that he might interpret them; and that his interpretations were not obscure and ambiguous, but clear and direct. He seems to have obtained a very easy and ample livelihood by this profession. The superstition of the Romans respecting dreams seems to have been at its height in the time of Augustus. This emperor not only observed the time of the year when his dreams were least favourable and most uncertain, but on a certain day of every year, in consequence of a vision, he begged publicly, stretching out his hand to those who reached him a few *accet,* and in his reign a law was passed obliging all who had dreamt anything respecting the state, immediately to make it known, either by a placard, or by the public crier. The consequence was, that dreams multiplied so excessively, that it was necessary to adopt it as a principle, that none which related to the state should be regarded, unless they were seen by magistrates, or at least by more than one individual. It has been remarked, that, with respect to these superstitions, the most polished nations of antiquity approached very nearly the Indian tribes of North America. "All the marches of the Indians are regulated by the dreams of the old warriors, who, under this pretence, often convey information, gained by spies, to the young men; but it must be observed, that they only pay attention to dreamers of established character." See Ferrar on "Popular Illusions," p. 28.

But though the superstitions notions which the ancients entertained on the subject of dreams, naturally and necessarily dissipated or disabled them from investigating their real cause and phenomena so clearly and fully as they might otherwise have done, yet some of them have offered hypotheses to account for them, certainly not less philosophical than many which have been brought forward by modern writers. These hypotheses, of course, resulted from, or rather formed, a part of their general system of physics and metaphysics. We shall briefly notice the most celebrated. According to Epicurus, our sensations are the effects of the different organs which the soul, while united to the body, is capable of employing, and of the different properties and qualities of external objects. These are rendered sensible, by means of certain species, or images, which are perpetually passing, like thin films, from bodies, in form similar to the surfaces of the bodies themselves, and striking upon organs fitted to receive them. The species, or images which produce these effects, are inconceivably small, and therefore do not, in passing away, perceptibly diminish the body; and from the innate tendency to motion in the atoms of which they are composed, they fly with inconceivable velocity from the object to the organ of sensation. From this general doctrine, Epicurus concluded, that sleep was produced, when the parts of the soul which, at other times, were diffused through the body, were repressed or separated by the action of the air, or of food; and that dreams were the effect of images, ca-
DREAMS.

1. In dreams every thing appears real; while our dreams continue, every thing which we see or hear— all the events in which we take a part, our sentiments, feelings, and passions, are exactly similar to those of real life. Our existence, in short, seems to be renewed, if, after a deep and sound sleep, we begin to dream. Addison has described the general fact with no less truth than elegance: "The soul in dreams converses with numberless beings of her own creation; and is transported into ten thousand scenes of her own raising: she is herself the theatre, the actor, and the beholder."

2. Our opinions, feelings, sentiments, and habits, in dreams, have a strict relation to our real character: we do not dream that we entertain or express those opinions which we do not actually believe; nor that we experience those feelings, to which we are strangers or adverse while awake.

3. In our dreams, we seem to have the idea of time. As this is doubted by some philosophers, it may be proper to adduce the particular facts on which it is grounded. In our dreams, we frequently anticipate or dread future events; and we experience regret for those that are past; we also consider one event as the cause of another; but, in all these cases, the idea of time is evidently implied.

4. We reason in our dreams. We frequently seem to hold an argument with others. "We address them in harangues, and write whole pages with greater celerity, than an author, in his happiest hours of inspiration, can connect as many sentences. Degrees of good and evil are compared in the same manner as in the business of the day. We conceive ourselves pursued by an enemy, with obstacles on every side, as rocks and rivers. We observe the dangers of each, and we choose that path which appears to us least dangerous." (Brown on the Zoology, p. 553.) Of these facts every one's experience must convince him; but there are others not so common, but which nevertheless seem well established; which prove that our inventive and reasoning powers are active and vigorous in our dreams. Condorcet told Cabanis, that while he was engaged in some abstruse and profound calculations, he was frequently obliged to leave them in an incomplete state, in order to retire to rest; and that the remaining steps, and the conclusion of his calculations, have more than once presented themselves in his dreams. According to Cabanis, Franklin's ideas respecting the perfection of the mental powers during dreams, were still more extraordinary than those of Condorcet; for that philosopher assured him, that the bearings and issue of political events, which had puzzled him while awake, were not unfrequently unfolded to him in his dreams. (Cabanis, Reap. Physique, et du Moral de l'Homme, tom. ii. p. 547.) And the writer of this article is acquainted with a gentleman of a very speculative and inventive turn of mind, to whom the idea of making a flexible rudder to ships, which, like the tail of fishes, might not only direct, but assist their course, was presented in a dream.

5. Our dreams are often wild and inconsistent.

6. Most people must have experienced in their dreams,
that absent or dead friends, the idea of whom they have in
vain endeavoured to recall while they were awake,

135

have appeared most distinctly and permanently; the
impression of them is strong and vivid, and while the
remembrance of the dream continues, their image is
present to the mind; but as soon as the recollection of
the dream vanishes, or becomes faint, that image can
no longer be called up, at least so distinctly and per-
manently.

7. Our sensations of pain and pleasure are fre-
quently very strong during our dreams, as we have already
remarked. Our peculiar character remaining in our
dreams, all the habitual opinions and feelings of our
mind are called up by the same circumstances, that
would excite them when we are awake; but in many
cases, our opinions are expressed with more vehemence,
and our feelings are more acute. Perhaps our sensa-
tions of horror are much stronger in dreams than they
ever are in reality; most people, we imagine, can at-
test the truth of this remark from their own experi-
ence.

8. The rapidity in the succession of our thoughts, or
of the transactions in which we seem to be engaged, is
often very astonishing, "in so much so, that when we
are accidentally awakened by the jarring of a door, which
is opened into our bed-chamber, we sometimes dream
a whole history of thieves or fire, in the very instant of
awakening."—Zoonomia, Section 18.

9. There is a vast variety of scenery, novelty of com-
bination, and distinctness of imagery, in our dreams;
and it may be remarked, that they consist chiefly of
visible imagery, and what we appear to see in our
dreams, impress us more strongly than what we appear
to hear or do. While we are awake, vivid impressions
are constantly made on the optic nerve; hence they be-
come more frequently and strongly the objects of our
dreams. It may be remarked in this place, that, ac-
cording to Parkehurst, the Hebrew word, which signifies
a dream, implies broken parts or fragments, composed
of ideas or images received by our senses, particularly
by our sight, while awake.

10. We are seldom surprised at the wildness or in-
consistency of our dreams. Some authors contend that sur-
prise never takes place: but this is evidently a mistake;
though it must be admitted, that those things which
would excite the strongest surprise while we were
awake, are generally regarded in our dreams without
any feeling of that nature. We are, indeed, very sel-
dom surprised, either at the inconsistencies in our
dreams, or at their presenting to us objects, which,
while awake, we should immediately know could not
appear to us. If the image of an absent or dead friend
appear in our dreams, we feel no surprise; we ex-
perience no tendency to doubt the reality of the appar-
erance; we converse with him; we seem to hear him
speak, and see him act, as if he were actually present
or alive; but if he utter sentiments, or perform actions,
different from those to which we have been accustomed
from him, then surprise is undoubtedly felt. But, per-
haps, it is still more extraordinary and inexplicable
phenomenon, that the inconsistencies and contradic-
tions in our dreams themselves should so seldom excite
surprise; that we should not feel surprised at the con-
tradiction between reality and our dreams, may easily be
conceived; but as we undoubtedly compare and reason
in them, it is extraordinary that the inconsistencies be-
tween parts of them should not be noticed, and excite
surprise; and yet scarcely any of the phenomena of
dreams are better established than the one to which we
are now advertung.

11. We have already observed, that Aristotle noticed
the fact, that we often dream that we are dreaming: in
many cases, however, where this is supposed to take
place, it is very probable that we are actually awake;
but for so short time, and in such an imperfect manner,
that we confound our waking thoughts with our dreams.
Smellie says, that men, who have the misfortune to be
subject to disagreeable dreams, learn by experience to
know that they are dreaming. He adds, "when ter-
rorized with impending danger, and even death, I have
often said to myself, 'Don't be so much alarmed: you
have been in the same, or in similar situations, which
were uniformly discovered to be dreams.' This species
of dormitory reasoning greatly alleviates the pain, and
not unfrequently gives an opposite direction to the
imagination." (Smellie's Philosophy of Natural His-
tory, vol. ii. p. 372.) There can be little doubt, that
what he calls dormitory reasoning was exercised du-
ing a moment of short and imperfect vigilance.

12. When our dreams are disagreeable, we seem to
be sensible of strong and painful efforts to free our-
selves from them, either by endeavouring to remove
from the scene where the disagreeable circumstances
occur, or (as it were) by changing our thoughts. Of
this latter mode of attempting to free ourselves from
unpleasant dreams, most people must have had ex-
perience; but whether it actually takes place while we are
asleep, or during a short interval of imperfect vigilance,
it is not easy to determine. With respect to our en-
deavours to quit the scene of unpleasant occurrences,
there can be no doubt that they take place in our
dreams; and it is equally true, that these endeavours
are for the most part unsuccessful; and we experience,
in our dreams, the painful impression, that, in spite of
all our efforts to the contrary, the most afflicting, dis-
agreeable, or horrid dreams continue to haunt us.

13. When we dream that we change our place, we
seem to be transferred by a kind of sailing or flying
motion. This, however, is not always the case: in
some instances, we are suddenly transported from one
place to another, without any intermediate impression
of the mode by which it takes place; while at other
times we dream that we remove from one place to
another by the usual modes of conveyance. When-
ever, however, the change of place is great and sud-
den, it is either accompanied with the sensation of a
sailing or flying motion, or seems to be effected in-
stantaneously, and without any motion.

14. We not unfrequently dream that we are falling
from a great height; and we seem to experience that
rapid whirling of the brain and senses, which must
take place when such a circumstance actually occurs;
but we believe it very seldom happens, that any person
under the influence of such a dream, ever seems to ar-
rive at the bottom: he feels himself moving in the air;
he even reflects on the consequences of his fall; he
shudders with horror; but before he seems to arrive at
the bottom he awakes.

15. Dr Darwin observes, "that if we sleep in the
daylight, and endeavour to see some object in our
dream, the light is exceedingly painful to our eyes;
and, after repeated struggles, we lament in our sleep
that we cannot see it."—When we are forcibly waked
at midnight from profound sleep, our eyes are much
dazzled with the light of the candle for a minute or
two, after there has been sufficient time allowed for
the contraction of the iris; but when we have dreamt much of visible objects, this accumulation of sensorial
power in the organ of vision is lessened or prevented, and
we awake in the morning without being dazzled with the
light, after the iris has had time to contract itself." (Zoönomia,
sect. xviii.) We give this circumstance on the
authority of Dr. Darwin; if correctly stated, it is
confirmed by no means general; but, as it is adduced
to support a particular theory, we should be disposed
to question its accuracy.

16. Our dreams more frequently relate to the scenes
and occurrences of childhood and early youth, than to
those of later years. This is the case, whenever no
particular circumstances connected with our bodily sen-
sations, our mental habits, or events in which we have
been deeply interested, do not give rise to them. Our
general dreams certainly present to us, in most in-
stances, what has happened in our youth. In this re-
spect they resemble the memory of old men, which is
usually more vivid and rich in the scenes and occur-
rences of early youth than of later years. Mr. Stewart
remarks, that in youth our dreams commonly involve,
in a much greater degree, the exercise of imagination,
and affect the mind with much more powerful emotions,
than when we begin to employ our more mature faculties
in more general and abstract speculations." (Philoso-
phy of the Human Mind, 4to edit. p. 392.) Hence, as
our dreams partake of our passions as well as our char-
acter, the dreams of those who are much engaged in
philosophical studies, relate chiefly to reasoning and
speculation, where the influence of particular circum-
stances does not operate.

All these facts regard the dreams themselves; but
there are others respecting the evident and immediate
causes of dreams, or which relate to our impressions
and feelings, when we awake after dreaming, which
require to be stated.

1. Our dreams are often caused by bodily sensations;
It has been already noticed, that Aristotle remarked,
that a slight heat applied to the feet, when we are asleep,
often produced in our dreams the feeling of burning
coals; and Mr. Stewart relates a similar fact respecting
a friend of his, "who having occasion, in consequence
of an indisposition, to apply a bottle of hot water to his
feet, when he went to bed, dreamed that he was making
a journey to the top of Mount Etna, and that he found
the heat of the ground almost insupportable. Another
person having a blister applied to his head, dreamed that
he was scalped by a party of Indians." Sometimes sen-
sations give rise to dreams in a more direct manner,
and more similar to themselves: Smellie mentions a
student of medicine in the University of Edinburgh,
who was accustomed to talk and answer questions in his
sleep; in consequence of which habit, some of his
friends whispered into his ear the name of a lady to
whom he was attached: at first he talked incoherently;
but soon his dreams evidently related to the object of
his affections: he thought he was under her window,
and he upbraided her for not appearing to him, as she
had frequently done before; at length becoming impa-
tient, he started up in his sleep, and threw whatever
he could lay hold of, against the opposite wall of his
chamber, evidently supposing it was the window of his
mistress's room: when he was told next day what had
happened, he said he had only a faint recollection of
having dreamed about his mistress. (Smellie, vol. ii.
p. 398, 399.) Beattie relates a still more striking instance
of the effect of sensations in producing dreams: A gen-
tleman in the army, was so susceptible of audible im-
pressions during his sleep, that by speaking in his ear,
his friends could make him dream of what they pleased:
One night they carried him through all the process of a
duel, and at last, putting a pistol in his hand, he actually
fired it off, and was awakened by the sound. (Beattie
on Dreams.) If the bed-clothes fall off while we are
asleep, we frequently dream that we are naked. In
some cases, impressions on our senses appear to mix
with our dreams; we frequently find the ineffectual
calls that are addressed to us, as well as other sounds,
mixing with them.

2. Closely allied to this cause of dreams, are the sen-
sations we experience from the state of the viscera, sto-
mach, &c. Perhaps the most singular circumstance
connected with the operation of those causes, is,
that an overloaded stomach sometimes produces dreams, in
which the person fancies himself strangled with reple-
tion, and at other times he dreams that he is dying of
hunger; but persons who have been deprived of their
usual food, generally dream of eating: Trench relates,
that being almost dead with hunger, when confined in
his dungeon, his dreams every night presented to him
the luxurious and well-plastered walls of Berlin, from
which he thought he was about to satisfy himself.
There are other causes, evidently connected with our
sensations, which give rise to dreams: these posture,
particularly too low, if we have too
many bed-clothes, or if any thing happens to obstruct
our respiration. It is well known also, that opium,
and other soporifics, if they do not produce very sound
sleep, give rise to dreams. Medical men remark, that
some tempers are more subject to dreams than
others; the sanguine more frequently than the phleg-
nic.

3. The character of our dreams is greatly influenced
by our disposition; hypochondriacal persons have often
anxious dreams, and cheerful persons cheerful dreams.

4. Our state of health seems to have considerable
effect, not only in producing dreams, but in giving
them their particular character. This fact is sufficiently
well known; and medical men remark, that acute
diseases, particularly fevers, are often preceded and in-
dicated by disagreeable and oppressive dreams.

5. Our dreams are influenced by our thoughts and
employments during the day, as well as by our general
habits of association and action. There are probably
few mathematicians who have not dreamt of an in-
teresting problem; and who have not even fancied that
they were investigating it with much success; the in-
stance of Condorcet has been already noticed. In like
manner, "those whose ambition leads them to the study
of eloquence, are frequently conscious, during sleep,
of a renewal of their daily occupations." Stewart, p.
330.

6. The particulars which pass before us in a dream
are often forgotten, till at a distance of time some anal-
ogous idea or transaction recalls them.

7. We are apt to confound the impressions we have
received in our dreams, with the thoughts and events
of real life; in some instances so completely, that we
are unable to determine whether we remember be
a dream or not.

8. Our mental feelings, as well as our bodily sen-
sations, to which dreams give rise, often remain in full
force for some time after we awake: Of this, so far as
respects bodily sensations, all must be sensible, who
have suddenly awakened from dreams of impending
danger or horror; and the same is the case, where the mental feelings of indignation or sorrow have been excited in our dreams, we are conscious of them for some time after we awake.

It is not easy to determine whether all men dream; it is more certain that some men are more subject to dreaming than others. Locke is of opinion that most men pass a great part of their sleep without dreaming: he adds, "I once knew a man, that was bred a scholar, and had no bad memory, who told me, he had never dreamt in his life, till he had that fever he was then newly recovered of, which was about the five or six-and-twentieth year of his age." (Locke, Book II. Chap. i. § 14.) The probability, however, is, that all persons dream more or less; since some of the numerous causes which produce dreams must operate in some degree, and at some periods of their lives, on all men; besides dreams are apt to be forgotten; and those who, by some subsequent occurrence, or train of thought, are reminded of their dreams, would, if this had not taken place, have conceived that they had not dreamt. It is more certain that very young children do not dream; at what age they generally begin has not been ascertained. Many animals undoubtedly dream: this fact was known to the ancients.

A much more curious and interesting question is, of what kind are the dreams of the blind, and of the deaf and dumb, especially of the blind? for we have seen that visible imagery constitutes by far the largest and most important portion of our dreams. Unfortunately on this subject we have very few facts; from these, however, we shall select two, which are given on good authority, and one of them rather in detail. Mr Bew, in his Essay on Blindness, published in the first volume of the Manchester Transactions, says, that a blind gentleman with whom he conversed, clearly proved, that in his dreams, he was conscious of the figure, though he could not distinguish the varieties of the human countenance; and that from the confused efforts he made to explain himself, it might be perceived that he felt himself alarmed with new sensations, that bore a strong relation to our ideas of light and colour, but which means he was unable to describe, because he could not fix on any comparative idea whereby to explain himself. These dreams were always painful, and the impressions extremely transient and unsatisfactory.

The other fact relates to Dr Blacklock. Dr Reid asked him if he had any idea of light? And upon his replying in the negative, he enquired if there was any difference between his ideas of persons and objects when he dreamt, and those which were excited while awake? Dr Blacklock replied the difference was great; but at first he was unable to explain it. At last, with some degree of exultation, he exclaimed, "Now I have it!" When he was awake, he could distinguish persons three ways; by hearing them speak, by feeling their head and shoulders, or by attending, without the aid of speech, to the sound and manner of breathing. But in sleep, the objects which presented themselves were more vivid, and without the intervention of any of the three modes, he had distinct perceptions of distant objects, both animated and inanimate. Being asked by what means he thought these impressions were conveyed to him? he replied, that he imagined his body was united to theirs by a kind of distant contact, which was effected by the instrumentality of threads or strings which proceeded from their bodies to his own, and that mutual ideas were conveyed by vibrations of these strings. (Smellie, p. 398, 399)

Having thus detailed the principal facts connected with dreaming, we shall conclude this article with a very brief summary of the opinions and theories which have been advanced by modern philosophers, either respecting the cause of dreams in general, or in explanation of some of its phenomena.

1. Wolfius, and after him M. Formey, maintain, that dreams in all cases are caused by impressions on the organs of sense. This theory has been confounded with that of Aristotle, from which, however, it differs very materially. The Grecian philosopher believed, that all impressions on the brain were conveyed by means of the senses, and that these impressions being called up again during sleep, produced dreams; whereas Wolfius and M. Formey are of opinion, that dreams are occasioned not by renewed impressions, but by direct impressions on some of the senses during sleep. That our dreams are caused or modified by our bodily sensations while we are asleep, we have already seen; but it does not hence follow, that in all cases they are produced in this manner; on the contrary, dreams frequently occur when we have no reason to suppose that any impression has been made on our organs. This hypothesis, therefore, is completely gratuitous and un-founded.

2. Sir Henry Wotton seems to have been of opinion, that during sleep the soul exercised a freer and wider range; or, as he expresses it, it had then a "moredetector operation." This notion, borrowed from the ancients, and to which we shall afterwards have occasion more particularly to advert, will, we apprehend, in the present day gain few believers. Sir Thomas Brown, however, entertained a similar opinion. The sumbmers of the body, according to him, were but the working of the soul; "the ligation of sense, but the liberty of the soul;" and he appears to have grounded this opinion on the fact, "that our waking conceptions do not match the fancies of our sleep." (Helieuale Wottoniana, and Religio Medicci, tom ii. p. 11.)

3. Mr Hobbes thought, that in all cases dreams were produced either by some particular disorder, by a general bad state of health, or by unpleasant bodily sensations. He has evidently fallen into the same erroneous mode of reasoning as Wolfius and M. Formey; that is, he has drawn a general conclusion from particular facts. Disease, an unhealth or bad state of the body, and unpleasant bodily sensations undoubtedly give rise to dreams; but hence it by no means follows, that these are the only causes of dreams. Mr Hobbes mentions, that lying cold produces dreams of fear. In some cases it may; but, in other cases, it either gives rise to no dreams, or to dreams of a different character.

4. Andrew Baxter, the author of Matha, entertained a very whimsical theory on this subject. He believed that dreams were produced by the influence of unembodied spirits on the mind during sleep. This theory he adopted, in consequence of our dreams appearing to be obstructed upon us against our will, and all our efforts, by some external cause. (Baxter on the Soul; chap. x.)

5. Haller, and some other physiologists, are of opinion, that dreams never accompany sound sleep. They therefore suppose them to result from some strong stimulating cause, or some forcible impression excited by the influence of undigested food.

6. Locke does not, strictly speaking, endeavour to account for dreams. He only explains what he conceives to be their nature, and that incidentally and briefly, "The dreams of sleeping men are, as I take it, all,
made up of the waking man's ideas, though for the most part oddly put together." And again, "Dreaming itself, is the having ideas (whilst the outward senses are stopt, so that they receive not outward objects with their usual quickness,) in the mind, not suggested by any external objects or known occasion, nor under any choice or conduct of the understanding." (Book ii. ch. i. § 17, and ch. xix. § 1.)

Opinion of Bonnet.

7. The theory of Bonnet is similar to that of Sir Henry Wotton; but as the character of the former writer stands high for physical and metaphysical knowledge, it may be proper to state and examine it more fully than we did when we noticed it before. Bonnet inquires how it happens, that the perceptions of the soul during sleep are so vivid? To this he replies, that we can discover the cause only in the silence of the senses. While we are awake, the senses mix in a certain degree with all the operations of the soul; but when we go to sleep, the perceptions from without grow feeble, and the perceptions from within become more strong and vivid; and as soon as the senses are hulled into profound sleep, then the soul is perfectly awake and busy, and renders us conscious of its operations in what we call dreams. Besides this general theory to account for dreams, Bonnet endeavours to explain the singularities and inconsistencies which take place in them. Notwithstanding the great power of the senses, and the unfettered vigilance of the soul, it sometimes happens that external sensations, though feeble, mix even in profound sleep, with the more vivid operations of the soul, and hence all the inconsistencies and vagaries of our dreams. The following remark, though rather fanciful, deserves quotation: "Since then our dreams, in general, are only the representation of objects, which have interested or occupied us while awake, let us endeavour so to regulate our imagination, that we may only have rational dreams; thus shall we be enabled to prolong the duration of our intellectual existence, (de notre etre pensant)" (Contemplation de la Nature, chap. vii.) It is unpleasant to deal hardly with a theory supported by such a man as Bonnet, in whom amiableness of disposition, fervency and at the same time rationality of piety, and a very minute and extensive knowledge of nature, always brought forward for the most devout and sublime purposes, were united in an uncommon degree; but his theory of dreams does more credit to his imagination than to his philosophy.

Opinion of Hartley.

8. Hartley endeavours to explain the principal phenomena of dreaming, by his peculiar theory of vibrations. That the scenes in them are mistaken for real, is owing, according to him, to the exclusion of real impressions with which they may be compared, and to the increased vividness in the trains of visible ideas. Dreams are wild and inconsistent, because the brain is in a very different state from that of vigilance, and the vibrations of the stomach being propagated to the brain, produce a succession of ideas, which depend indeed upon association, but are very different from those which would take place in a state of vigilance. We are not offended at inconsistencies, because those associations which should lead us to notice them are as it were asleep; but if the state of the brain be such as to favour the production of ideas of anxiety and perplexity, apparent inconsistencies give us great uneasiness. When persons walk and talk in their sleep, the vibrations descend into the motory muscles, at the same time the brain is oppressed, and they have no memory. Dreams are soon forgotten, on account of their incoherence, and of the change which takes place in the brain in passing from sleep to vigilance. From this specimen of the mode in which Hartley attempts to account for the phenomena of dreaming, it is evident, that what he deems explanations, are either mere emendations of the facts to be explained in different words, or completely gratuitous and unphilosophical. (Hartley on Man, Part i. ch. 2. § 5.)

9. Dr Darwin has directed his attention rather to the Of Darwin state of the mental faculties in sleep and dreams, than to their cause. He is of opinion that volition is suspended, and that sensation continues. We shall briefly notice some of the principal facts and arguments by which he endeavours to support this doctrine, and the very acute and forcible objections which have been made to it by Dr Thomas Brown, professor of moral philosophy in the university of Edinburgh, in his Observations on Zoornia. To the general doctrine of Darwin, that the power of volition is totally suspended, Dr Brown objects, that as the trains of ideas which constitute our dreams were originally associated when we were sensible of external objects, and consequently when volitions formed part of the train, if the laws of association continue during our dreams, (which Dr Darwin does not deny,) volitions should be induced, whenever the preceding motion of the train exists. If volition were suspended, our dreams could only occupy a few minutes of our sleep, since our associations would be suddenly broken off at that part of the train which was originally succeeded by volition; for the motion consequent on volition could not be produced, according to the known laws of association, unless volition existed. Dr Darwin says, that "during the suspension of volition, we cannot compare our other ideas with those of the parts of time in which they exist; that is, we cannot compare the imaginary scene which is before us, with those changes of it which precede or follow it, because this act of comparing requires recollection or voluntary exertion; but we evidently have the idea of time in our dreams, and as we reason in them, or, in other words, perceive the agreement or disagreement of ideas, recollection or voluntary exertion cannot be suspended. The instances which he adduces of motions of the larger muscles, the indistinct sentences which are sometimes uttered, and the confused barking of sleeping dogs, it is well remarked by Dr Brown, prove that the suspension of the voluntary power is not necessary to sleep. Indeed, besides those operations of the body or mind of which we dream, and which imply volition, we are frequently directly conscious of exerting it in our dreams, especially when they are unpleasant. That this exertion of volition is not followed during sleep by the same effects as it produces when we are awake, is no proof that it does not take place. (Zoornia, vol. i. § 18.) Brown's Observations on Zoornia, § xi.)

10. Professor Dugald Stewart has considered dreams of Stewart in a more cautious and philosophical manner than any other writer on the subject. He is of opinion, that "the power of volition is not suspended, but that the will loses its influence over those faculties of the mind, and those members of the body, which during our waking hours are subjected to its authority." In support of the latter part of this doctrine, he argues, that if the influence of the will be suspended during sleep, all our voluntary operations must also be suspended, such as recollection, reasoning, &c. That our recollection is suspended, is evident from our dreaming of seeing persons who are absent or dead, and from our confounding times and places. To the objection that we reason in our dreams, he replies, that these reasonings...
are carried on independently of any exertion of the will. His second argument is, that if the influence of the will during sleep be suspended, the mind should remain passive; and that this is the case in our dreams, has always been considered as one of the most extraordinary circumstances with which they are accompanied. It is indeed a matter of vulgar remark, that our dreams are in every case involuntary on our part; not that we do not exert volition in our dreams, especially, as has been already stated, to remove unpleasant images, but that the influence of our will is then suspended. Besides, Mr. Stewart argues, that, if his opinion be well founded, the conceptions which we form during sleep of sensible objects, will be attended with a belief of their real existence as much as the perception of the same objects is while we are awake; and this is an undoubted and well known fact. (Stewart's Philosophy of the Human Mind, 4to edit. chap. v. sect. 5.)

Of Cullen.

11. Cullen was the first who pointed out the constant and regular resemblance between dreams and delirium; and who proved, that, at the commencement, and during the continuance of sleep, the different senses and organs sleep successively, and in a very unequal degree; and that the partial excitation of those parts of the brain, which correspond to them, by disturbing the harmony of its functions, produces irregular and confused ideas, which have no foundation in reality. This doctrine of Cullen has been adopted by Cabanis, who enters into it more minutely and fully. As his remarks on the subject are, we believe, very little known in this country, we shall conclude this article by a brief abstract of them, so far as they regard, and in his opinion explain, the phenomena of dreams. Before, however, we give his observations on dreams, it will be proper to attend to what he says respecting sleep. In illustration of Cullen's doctrine, that the senses and organs fail to sleep successively, he observes, that the muscles which move the arms and the legs relax, and cease to act, on the approach of sleep, before those which sustain the head; and these before those which support the back. At the period when the sight, under the protection of the eye-lids, no longer receives impressions, all the other senses preserve their sensibility entire; the sense of smelling does not fail asleep, till after the sense of taste; the hearing, till after the sense of smelling; and the sense of touch after the hearing. This last sense appears to be awake, even during the most profound sleep; for we exercise it, when we change our position in bed, which often takes place without in the smallest degree disturbing our sleep. Nor do the senses sleep equally profoundly. The sense of taste and smelling awake the last: the sight seems to awake with more difficulty than the hearing; the smallest noise will sometimes awake somnambulists, on whom the most vivid light makes no impression, though their eyes are open. The sleep of the sense of touch is more easily disturbed than that of the hearing; the same person who would not be awakened by noises very sudden and loud, starts up immediately if the soles of his feet are tickled in the slightest degree. The same is the case with respect to the internal organs; the viscera fail to sleep one after the other, and sleep with different degrees of profundity.

Of Cabanis.

The truth of these observations, Cabanis confirms by what happens to somnambulists, and cataleptic patients. He also remarks, that in different persons the different muscles seem to fall to sleep at different periods: some can sleep on horseback; with them the voluntary power over the muscles of the back is retained and exercised during sleep; others sleep standing, or even while they are walking. Hence this author infers, that volition exists and is exercised during sleep; and the accuracy of it he thinks is further proved by the facts, that a person while in this state puts up his hand to drive away the fly that may have settled on his face; pulls the bed-clothes upon him; and, as was before observed, changes his position in bed.—But besides these facts respecting the successive order, and the different degrees, in which the organs and the senses sleep, there is established among them, while they are in this state, new sympathies and relations, with respect to the impressions which peculiarly belong to them. Hence their influence on the brain is different from what it is when we are awake; thus, the process of difficult digestion gives rise to different images in the brain during sleep, from those which it would produce in our waking state.

Having premised these observations, Cabanis next enquires, by what kind of impressions, and by what state of the animal economy, are dreams produced? To this he replies, that they evidently take place when the action of the external senses is suspended; that of most of the internal organs moderated, but in a different degree; the sensibility of some of them being even increased: in this state, a large portion of the nervous influence is concentrated in the brain, which is given up either to its own peculiar impressions, or to those which it receives from the internal organs, which still exert their influence without the intermixture of impressions from external objects, which might give them order and consistency. The compression of the diaphragm on the process of digestion often recalls, in our sleep, forgotten events, or persons, or trains of reasoning, by acting on that part of the brain where the impressions of these objects were formerly excited; for it is not true, that our dreams relate only to those things which have excited our attention or interest while we are awake. Such, no doubt, from the power of association, very frequently give rise to them; but in many cases they can be accounted for only on the supposition that the brain, during sleep, is given up either entirely to its own peculiar impressions, or to those impressions which are excited or modified by the action of such organs as still retain their power. On this theory we shall only remark, that even if it is quite intelligible and satisfactory to the physiologist, it will not be received with much deference by the metaphysician. See Rapports du Physique, et du Moral de l’Homme, par P. J. G. Cabanis, toin. ii. p. 594—551. (w. s.)

DREDGING, is an operation of the utmost consequence to the improvement of navigable canals, rivers, docks, harbours, &c. and is performed by means of machines, of various construction, so contrived as to loosen and lift the mud, gravel, or other materials, which are occasionally deposited, or may have been the original stratum, under water.

As much depends on local situation with regard to dredging machines, like many other branches of civil engineering, it is difficult to give precise information on the subject, and a great deal must be left to the persons who are intrusted with the immediate direction of the works to be performed.

We shall endeavour, however, to give such general ideas, and accompany these with drawings of one of the most improved and powerful machines now in use in this kingdom, as, we hope, will render this article very valuable to the practical engineer.

We believe dredging under water was first resorted to by the Dutch, for clearing the bars or entrances to
their harbours and navigable canals. These early machines were not contrived for lifting stuff, but only to loosen it, that the sluices which were constructed for the purpose of scouring might be more effectual. The machine consisted of large bars or prongs, like a number of forks, placed vertically in a frame, and being fastened to a barge placed in the line of the sluices, the whole was impelled forward by means of the current, and caused a more powerful scour.

The first kind of dredging machines employed to any extent in Britain, consisted of a large plate of iron, about four feet long and eighteen inches deep, and sharpened on the under edge. To each end of this plate of iron, a plank of hard wood was fixed to tenons cut in the iron, the sharpened edge of iron projecting about four inches below the wooden sides, which should be about five long, tapering to ten inches deep at the point, where a bar of iron is fastened to keep the two ends asunder. The whole formed something like a box without bottom or top, eighteen inches deep at the one end, and ten inches at the other. From the two extreme points of the wood a chain is fixed for attaching the principal working rope or chain.

In order to put the machine in motion, it is requisite to have a punt moored on each bank of the river directly opposite, and on each of these punts a capstan or windlass, the one for drawing across the empty dredge, and the other for bringing it back. In the course of its passage, the dredge is generally filled, and by means of the capstan it is drawn so high up that men at low water can remove the stuff with shovels. Where the shiftings are not frequent, a capstan or windlass may be placed on the bank of a river, and the operation performed as before. But as the method by the machine just described, is very tedious where dredging of great extent is required, it is now little used except in levelling foundations under water, for which it is well adapted, if the material is soft sand or mud; but where there is stony gravel, it is necessary, in place of having the mouth of the dredge straight, to have it made with bars of iron curving towards the under edge, and placed about four inches apart, when stones of considerable size may be brought to the side, and removed in the manner we have already noticed. Machines constructed agreeably to the foregoing principle, have for many years been employed in deepening the navigable part of the river Clyde between Glasgow and Dumfries.

We come now to the operation of dredging, which is performed by the bag and spoon. This kind of dredging has been carried on to a considerable extent under the direction of the Trinity-house at London for deepening the river Thames, and also for obtaining ballast to the vast number of ships which frequent that noble river. The convicts at Woolwich have been long employed in the same manner for deepening the river, and obtaining stuff for embankments and other government works at Woolwich.

The spoon consists of a ring of malleable iron, two feet wide, and two feet four inches deep; sharpened and steadied on the under side four inches broad for about one-third of its circumference, and pierced on the inner edge with holes for the lacing of the bag. The remainder of the ring is of round iron one inch and a half diameter, and on the upper side, or that opposite to the mouth, a hose must be welded to receive the pole or handle, which, to a spoon of the above size, should be from four to five inches diameter; the length of this pole or handle will always be regulated by the depth of water. From each side, about half way up the spoon, a chain two feet and a half long is fastened, and these chains come together by a small ring in the middle, to the place where the working rope is made fast.

The bag is generally made of strong tanned leather. Bag of the size of the spoon at the mouth, narrowing considerably towards the bottom, that it may be the easier discharged. It is about three feet and a half deep, and is laced to the spoon with leather thongs, and perforated to allow the water to escape.

In order to work this spoon in navigable rivers, harbours, &c., it is necessary to have a flat built barge or lighter, from 30 to 50 tons burden, mounted with a small projecting crane work, made to throw out gear; and to within nine feet of this projecting crane, a rail should be placed to assist the spoon holder, and prevent him from falling over the barge. On the end of the barge where no crane is placed, a snatch block should be fixed, through which, and attached to the bottom of the bag, a small rope should be received.

The barge being thus mounted, and moored over the place where it is proposed to dredge, and one end of the working rope being fastened to the chain of the spoon, and the other end to the barrel of the crane, the man who is stationed at the handle or pole of the spoon immediately tumbles the spoon into the water. At the same moment the man at the crane work throws it out of gear, when the third man seizes the small rope, which is received through the snatchblock, and fast to the bottom of the bag, with which he runs along the gunwale, and prevents the spoon and bag from sinking until it gets near the other end of the barge, when the man at the pole turns it up, inclining the pole head towards the crane end of the barge, takes a turn with a small rope round the pole and rail, which keeps the spoon dredging along in its proper position, while the man at the crane, assisted by the other (who was employed at the snatchblock being now disengaged), draws along the spoon until it be nearly under the crane, when the man at the pole inclines it backwards, and the contents (now deposited in the bag) are hoisted up, and by their joint assistance emptied into the barge. A small tackle of pulleys may be suspended from a beam to empty the stuff into the barge. When the bag is discharged, they proceed as before, until the barge is loaded.

The bag and spoon dredge may also be successfully employed in dredging the foundations of bridges, &c., by erecting a platform to answer the purpose of a barge. The platform may be projected as the work advances, and the stuff taken up removed from the platform by a gangway and wheel barrows, where it cannot be otherwise disposed of.

In a commercial country like Britain, where ships have been gradually increasing in size, and more especially where harbours have little rise of tide, it is a matter of the greatest importance to construct dredging machines, which will increase the depth under low water of spring tides, in a more speedy and effectual manner than any we have yet described; and it is a fact well known, that all rivers, harbours, and canals, have a tendency, less or more, to fill up. Dredging machines should be like the tools of a perfect workman, never out of order.

Improved dredging machines on the principle of an endless chain, have been undergoing such improvements as experience has pointed out; and it may not be deviating from our general plan, to remark, that when these machines were first constructed, horses were employed as the moving power, and had a circle ap-
DREDGING.

Steam dredging engine.

The frame.

The chain of buckets.

propriated to them on board of the barge, that carried the machinery; and it was usual to have the horses so taught, that by the ringing of a bell they would immediately stop. One of these was long employed on the river Humber at Hull, and one at Port Glasgow; and there have been two constructed on the principle of an endless chain at the port of Greenock, the moving power being communicated by men and crane-work. The barges for these two last are built very flat, and square at both ends, and have an aperture up the middle, through which the bucket frame works, and the stuff is discharged over the end. This scheme answers very well on a small scale, but would not be advisable for a large machine.

As the recent improvements on steam engines have rendered them of the greatest value, particularly in a country which abounds with coal, every other moving power for dredging machines is rapidly giving way to the steam engine. Several of these have been for years employed on the river Thames, one at Hull, one at Bristol, one at Sunderland, and one at Aberdeen; and we understand they are now constructing several for dredging the entrance from the sea, and from the locks or lakes to the locks on the Caledonian canal. In one of these, the bucket frame will project considerably before the barge on which it is mounted, and be capable of sloping up canal banks, or, in other words, to work away high ground, and make a passage for the barge to follow.

In order to give our readers a more distinct view of this important branch of hydraulic engineering, we shall particularly describe one of the most powerful and most improved machines now at work on the river Thames.

One of the most powerful of these machines is explained in Plate CCXXXIX, where Fig. 1. represents an elevation and partial section of the machine, to explain the steam engine and wheel work contained in the inside of the vessel. Fig. 2. is a horizontal plan of the same. The machine is erected in the hulk of an old sloop of 50 or 100 tons burden, the figure and parts of which are too clearly explained by the drawing to require any particular reference. There are two chains of buckets to this machine, one on each side of the vessel, though only one of them is shown in Fig. 1. at EE, the other being omitted to make room for the small Figures. The endless chains revolve over rollers situated at the two extremities of strong frames of timber, marked EE, which rise and fall on a centre at their upper ends, their weight being suspended by pulleys aa, which being lowered down, permit the buckets ff, attached to the chain ee, to reach the bottom.

AA are two beams projecting a short distance from the sides of the vessel at the stern, upon which the two triangular timber-frames BB are mounted, to sustain a strong timber C extended across the vessel; these, with their cross timbers JJ, form a frame which supports all the machinery that is above deck. The beam C is as long as the whole width of the machine, and upon each end it has a cast iron bracket DD hanging downwards, as seen at D. These brackets support the upper end of the bucket frames EE, and also the centres for the chain barrels, over which the endless chains revolve by the motion of the machine. The bucket frames EE are each composed of four long timbers, bolted together, and braced by diagonal stays dd, forming a truss frame, which has sufficient strength to prevent flexure from its own weight. The pulleys aa suspending the lower end of the chain frames, hang from the beam FF, which extends across the vessel, supported on the top of two or three vertical posts erected on the deck. The upper end of each of the chain frames EE, has two stout iron semicircles bb bolted to the timbers, and terminating in rings or eyes fitted over two tubes or hollow iron centre pins, one supported by the bracket D, and the other by the frame B. On these pins the frame hangs as upon a centre at c, and can be raised or lowered as before mentioned. The upper roller for the endless chain, which is a square barrel, revolves upon the same centre of motion as the frame at c, and a similar square barrel of the same dimensions is placed in bearings at the lower end of the bucket frames, as seen at H in Fig. 1.; then the double endless chain e e e passes round both these barrels, and every other link of these two chains carries one of the buckets ff, which are made of wrought iron, as shewn on a larger scale at Fig. 3. They are pierced full of holes, to allow the water to drain out of the gravel as they come up: their mouths are of a semicircular figure, which renders them less liable to stick fast in the ground than if they were square. e. e. Fig. 1. represents a number of cast iron rollers placed on the inside of the beams of the chain frame, to support the weight of the chains and buckets as they pass up; for being very heavy when they are full, a great friction would otherwise be occasioned by the buckets dragging on the timbers.

The upper chain barrels for the frames on both sides of the vessel are in a line with each other, and both receive their motion from the steam engine, which is situated in the hold of the ship. Its parts are as follows: x, Fig. 2. is the boiler set in brick work, with the fire place beneath it; and a wrought iron tube Y, carried up to a high position, serves for the chimney, and is firmly braced by iron chains in different directions; z, Fig. 2. is the steam pipe communicating from the boiler to the engine, which is on Watt and Boulton's principle; P is its working or steam cylinder; Q the working beam or great lever, which is made of cast iron; its centre being supported on the top of four iron columns III, which stand upon the floor of the engine S. The connecting rod T of the engine is jointed to the extremity of the beam Q at the top, and the other end to the center of the shaft O. For a more minute description of the engine, which acts in the same manner as any other made by Watt and Boulton, see Steam Engine.

The fly-wheel V of the engine is turned by the large spur-wheel W, fixed upon the shaft O, acting in a pinion on the axis of the fly-wheel, to give it a greater velocity than the crank, by which means a smaller fly-wheel is made sufficient to regulate the motion of the engine.

The motion is conveyed from the engine to the chain wheels by an inclined shaft L, seen more plainly in the plan. At the lower end it has a bevelled wheel M, receiving motion from the wheel N, fixed on the main shaft of the engine. At the upper end of the same inclined shaft is a bevelled wheel K. Fig. 2. working another, J, fixed upon a shaft, situated in a line with the centre of the two chain barrels. At the two extremities of this shaft, two circular iron plates, or wheels, are fixed at ii; these are received into boxes, or hollow wheels, which are fixed on the extreme ends of two other shafts, placed in a line with the former, and leading to the chain barrels. These boxes and wheels form a connection between the several parts of the shaft; and by the friction of the wheels, which are accurately fitted into the boxes, a sufficient power is communicated to turn...
the chain barrels round, and bring up the gravel; but in case the buckets should take hold too deep in the ground, so as to endanger the breaking of the machine, these boxes will slip, and thereby prevent the chain from being broken. The construction of one of these boxes is explained more particularly in Fig. 4: it consists of a cast-iron wheel \( l \), wedged fast on the end of the shafts \( m n \), which is that in the middle of the ship carrying the wheel \( l \). The other wheel, or box \( k \), is cast hollow, as shewn in the section; and the first, \( l \), fits into it, being kept in its place by two ears \( o o \), screwed on by two bolts. These pressing hard against the rim of the wheel \( l \), causes a considerable friction, which will carry the shaft \( m \) round in its fair work, but if over-stretched, will slip. \( m n \), Fig. 2, are levers, which operate upon coupling boxes on the main horizontal shaft, and give the means of disuniting either of the chain barrels at pleasure, if one of them needs repair, whilst the other continues its work. The blocks of the pulleys \( a a \), which suspend the great bucket frames, are received with a chain, the fall of which passes through the snatch-block \( r \), fixed down upon the deck, and then winds round the roller \( s \). This is turned by the engine, the axis of it having a worm-wheel \( t \) fixed upon it, turned by the worm \( v \), which is seen endwise in the plan, and shewn on a larger scale at Fig. 5. This worm is in reality formed upon the inclined spindle \( l \), though it could not be shewn in the true place without making a confusion. Either of the bucket frames can, as before mentioned, be thrown out of gear, or stopped by clutch boxes, to the lever \( m m \), Fig. 2.; and then the lower end being hauled up by the pulleys \( a a \), till it hangs in a horizontal position, will be very accessible, to repair the chain, or any of the buckets, which frequently meet with injuries from obstacles at the bottom of the river.

The mode of action in this machine is evident from its structure: it is moored in the stream by the head or stern, or both, in some situations, if it is required to work across the stream. The engine being put in motion, the chain-frames are lowered down, by giving out the chains of the pulleys \( a a \), until the buckets drag sufficiently upon the bottom, to become filled with ballast in their passage, and come up along the top of the frames, by the motion of the chains, till they turn over the second, or chain-barrel, of the vessel, or for the sake of emptying the second barrel of the vessel. They then pass into large hoppers, or troughs, which are suspended by ropes from the beams \( B B \) and \( C C \); and being placed rather inclined, the troughs conduct the gravel into barges, which are moored beneath the extremity of them. Neither of these hoppers, or troughs, are shewn in the Plate, as they would tend to confuse the parts of the machine. The motion of each barrel is managed by a single man: he stands near the end of a long lever, which supports the pivots of the worm-wheel \( t \), so that, by moving the end of this lever, the wheel can be disengaged from the worm at pleasure, to give it motion, or set it at rest. There is also a gripes, or brake-wheel, not shewn in the Plate, fixed upon the spindle of the roller \( z z \); and the grip is so forcibly grasped upon it by a loaded lever, as to prevent the roller running back by the weight of the chain frames, even when the wheel \( t \) is disengaged from the worm. The wheel \( t \) is attached to its spindle only by the friction arising from its fitting on a circular part, so that it is at liberty to slip, if overstrained, without breaking the teeth; but it is provided with screws, as shewn in Fig. 5, which may be adjusted, to give sufficient friction to raise the load it is required to take up without slipping.

The attendant has the management of both the levers above-mentioned; and by means of them, he can cause the buckets to go just as deep as he wishes, to take up the proper quantity of ballast; and as they deepen the channel, he gradually cases the grip-lever, which permits the frame to descend lower down; but if at any time the buckets meet with an obstacle, or take such deep hold as to stick fast, (which they will do, without stopping the engine, because of the slipping box, Fig. 4,) he engages the wheel \( t \), with the worm, by means of the lever for this purpose, and this winds up the chain of the pulleys \( a a \), till the end of the frame is raised so high from the bottom as to disengage the buckets, which then resume their motion; and the wheel \( t \) is to be immediately cast off from the worm, because it is unnecessary to raise the frame any higher; but it may, if required, be lowered down to reach the bottom again, by relieving the brake-lever. In this manner, the operation proceeds with the greatest safety and dispatch. There are two other rollers similar to \( t \), situated just above the deck, and kept constantly in slow motion by the engine, for the purpose of advancing the engine along in the water. Thus, a strong rope is attached to a mooring block or anchor, placed at some distance up the stream, and is passed once or twice round the roller; then a labourer holds on the end of the rope, in the same manner as is done by a capstan; and thus the whole engine is slowly brought up, as the channel is dredged, and constantly advanced to operate upon a fresh part of the bottom.

The engine is of 16 horse power, and when dredging in a moderate depth, will bring up enough to load two barges, 35 tons each, in an hour, with only three or four men to attend the whole; and the engine will consume about 349 lbs. of Newcastle coals per hour.

Before concluding this article, we are desirous of recommending to those who intend to construct barges for carrying dredging machines, that no expense should be spared in having them built in the most substantial manner; for after the apparatus is erected, the smallest twisting of the barge may be the means of breaking parts of the machinery. Machines on the same general principle may be erected on any scale, and to dredge in any reasonable depth of water. This depends entirely on the length of the bucket frame \( m \), which will be that work best suited for barges of 45 ft. long. We may further remark, that when it is intended to dredge in shallow water, regard must be had to the construction of the barge, which should be broad and flat, and of a small draught of water, which will give more time to work, as they can only work whilst the barge is afloat. We may also notice, that machines on the foregoing principle work very well with a bucket frame on one side only, which is a considerable saving of expense. Upon the whole, these machines are capable of bringing up sand, mud, clay, or gravel; and even stones of considerable size may be taken up, as has been done at Aberdeen, without the smallest risk to the machine, when properly managed. (J. F. (W. G.)

Dresden, Dresden, Dresnem, Dazene, Dazonech, and Dresena and Dresda in Latin, is the capital of the kingdom of Saxony. It is situated in a rich and fertile country, on the banks of the river Elbe, at its junction with the Weseritz, and is divided into two parts, called the old and new town, by the first of these rivers. The town properly consists of three parts, Old Dresden, with its three suburbs; the new-town, (Neustadt,) which received this name from Augustus 11.; and the Freckenstadt or Ostra, which
is connected with the suburbs of Old Dresden by a stone bridge over the Weisseritz. The bridge which unites the old and new town, and which has been either destroyed or greatly injured by the French in 1813, was reckoned one of the finest in Europe. It was built of stone, and consisted of nineteen extremely flat arches; its length was about 707 ells, and on the fifth pier was placed an instrument for measuring the height of the river. Augustus II. furnished the bridge with footpaths, and adorned it with an iron balustrade, with vases, trophies, and lamps. The streets of this city are sixty-one in number, and are straight, spacious, well paved, and well lighted; and the houses are in general high, well built, and commodious. The town contains several handsome squares, and many elegant public edifices.

The royal palace, formerly the electoral palace, is a very fine building, and owes its chief ornaments to Augustus II. The floors are principally of exquisite marble, and the walls are covered with mirrors.

The green room, or vault, which contains eight rooms, is particularly splendid; and the hall of the giants, the hall of audience, and the chambers of parade, are worthy of peculiar notice. The tower of the palace is 355 feet high, exclusive of the conductor. The green room contains a prodigious number of natural and artificial curiosities.

The celebrated gallery of pictures occupies the second floor of the palace. It consists of several rooms communicating with one another in a circular form, and contains 1200 paintings, by 334 masters of the principal schools of painting. All of these are originals, and are admirably preserved. Besides many pieces of German, Flemish, and Dutch painters, the gallery contains the best works of Hannibal Caracci, Raphael, Guido, Albani, Leonardo da Vinci, Vandyck, Titian, Andrea del Sarto, Rembrandt, Carraraggio, Tintoretto, Nicolas Poussin, Luca Giordano, Corregio, Battori, and Rubens. The Night and the Magdalen of Corregio are greatly admired. A list of the principal pictures will be found in Naudiz's Travels, vol. ii. p. 309. In the year 1806 this gallery was enriched with a large historical painting by Fr. Mathew, with twelve figures, representing Egistheus punished by Orestes and Pylares in the palace of Agamemnon.

The palace of Prince Antoine is situated in the Faubourg, and that of Maximillian, which is a small though a light and elegant building, is situated on the other side of the bridge.

The Japanese palace, or the Dutch palace as it is often called, stands in a most picturesque situation, elevating its majestic domes among the boughs of trees. It is a large square building, and was intended by Augustus III. for a Chinese palace. The garden is small, and at the end of it near the water is a terrace, which commands a delightful view of the city, the river, and the environs of the town. The ground floor of this palace is devoted to the collection of antiques, which fills a long suite of rooms. It was formed between 1720, and 1739, by Augustus III., who purchased the greater part of the gallery of Prince Chigi, at Rome. He paid 6000 ducats for the vases of porcelain made at Rome, and painted by Raphael, and he also bought from the elector of Brandenburg two porcelain vases from Japan. The collection of porcelain is reckoned the finest in Europe, and consists of several millions of pieces of all kinds, from every country, and of every age. Mr Lemaistre, who has given an account of several of the arti-
cles in this cabinet, considers it as the finest which he has seen, excepting the collection of antiquities at Paris. The three Grecian statues of females, which were found in the first excavations made at Herculaneum, in 1760, are particularly admired.

The two upper floors of this palace are appropriated to the public library, which contains above 150,000 volumes, and 2000 manuscripts. The books are kept in high order, and the library is open several days in the week to the public, who are even allowed to carry the books to their own houses.

The Tresor, or the collection of jewels, contains a vast assemblage of diamonds, and other precious stones, and innumerable curiosities in ivory, enamel, coral, and Jasper, with clocks and other mechanical instruments.

The gardens called Der Zwinger, which form a kind of public promenade, contain several unfinished buildings, which were intended by Augustus II. to form part of a magnificent palace. The architecture is loadd with ornaments, and many of the buildings are in a state of ruin. These buildings contain a cabinet of prints and designs, which is deemed one of the finest in Europe, and contains specimens of the art from its infancy to its present state; a cabinet of petrifications and incrustations, and other objects of natural history; a cabinet of anatomical preparations; and a saloon of mathematical and physical instruments. The other public buildings, are the large and the small opera house, the assembly-rooms, the arsenal, which contains the first fire arms invented by Bertholde Schwarze, the military academy, the carousel, the barracks, the mint, the landing or state house, the royal China warehouse, the hotels of Schoenberg, Saul, of the Countess of Mokenska, of Flemming, of Anholt, of Vitzthum, of Bruhl, of Cosel, and of Marcolini, the last of which is remarkable for its furniture, its pictures, and its gardens, and for the colossal groupe of Neptune and his court. The hotel of Count Bruhl is now employed as a depot for the porcelain manufactures; but the garden is open to the public, and forms a delightful promenade on the banks of the Elbe. The carousel, or the court where tournaments and battles with wild beasts were formerly exhibited, appears to have been once a fine edifice, but it is falling rapidly to decay.

Dresden contains about 18 churches, the most remarkable of which are, the church of the Holy Cross, the church of the Catholics, the church of the Court, the church of Notre Dame. The church of the Holy Cross is an enormous circular mass of stone, and the painting at the great altar was executed by Schoenborn. The church of the Catholics, built by Augustus III. between 1737 and 1756, is one of the finest in Germany, and the handsomest building in Dresden. It stands delightedly on elevated ground, nearly fronting the bridge over the Elbe. Its organ is the chef-d'œuvre of the celebrated Silbermann. It is decorated by several admirable paintings by Meugs, a native of Dresden, among which is the Ascension, which is reckoned his chef-d'œuvre, and adorns the principal altar. The tower is 303 feet high, and the total expense of building it and the church was 906,955 rix-dollars. The church of Notre Dame, or St Mary's (Frauen Kirche,) was built in 1734 by Augustus II. on the plan of St Peter's at Rome. It cost 300,000 rix-dollars. From the lantern of the cupola the view is universally admired.

The literary and charitable establishments are numerous and well managed. The principal of these are the academy of painting and architecture, the annual exhibi-
DREUX, Dircasses, or Durcasses, is an ancient town of France, situated in a district of the same name, in the department of the Eure and Loire. It stands in a fertile valley on the river Blaise, at the foot of a mountain, and is supposed by some to have derived its name from the Druids. It is celebrated for the great battle which was fought in the neighbourhood in 1562, under Charles IX.; when the Protestants were routed, and the Prince of Condé taken. There are several manufactories for woollen and linen cloth, hats, and stockings, at Dreux, and some tanneries, besides a manufactory for cloth for the clothing of troops. Population 5437. (n)

DRILL PLough. See Agriculture, Index.

DRIMIA, a genus of plants of the class Hexandrhi, and order Monogynia. See Botany, p. 183.

DROGHEDA, or Tredagh, as it was once called, is the name of a borough town in Ireland, situated between the counties of Louth and Meath, and possessing the privileges of a distinct county. It stands on both sides of the river Boyne, at the distance of about 5 miles from the Irish Sea. The town is large and well built, and is still surrounded with the greater part of the walls by which it was formerly defended. From the rapid ascent of the ground on both sides of the river, the houses stand on different levels, and show the town to great advantage. Although Drogheda is a bad harbour, yet it is a place of considerable trade. It lies opposite to Liverpool; and the river is navigable for ships of 150 tons burden up to the town, where there is a handsome and convenient quay for receiving them. Great quantities of corn are shipped here, and coals are imported to a great extent, and conveyed by the river into the interior, and by means of a canal as far as Navan. There is a licensed distillery in the town, and a well endowed school. A great deal of coarse linen and linen yarn is sold here, and the markets are plentifully supplied with provisions. The town is governed by a mayor, sheriffs, and a common-council. The corporation is large, and the body of freeholders numerous; but the borough is under no political influence.

The four mills of Slane are about seven miles distant from Drogheda, and they communicate with it by water carriage. Mr. Beaufort states the population of this town at 15,000, reckoning 6½ individuals to every house. During the rebellion, when the names of the inhabitants were affixed to the door-posts of every house, the average of individuals in each house was 8½ in the town, and 5½ in the suburbs. The inhabitants are principally Catholics; and are remarkably poor. See Beaufort's Memoir, &c. and Wakefield's Statistical and Political Account of Ireland, passim. (n)

DROITWICH. See Worcester.

DROME, is the name of one of the departments of the south of France, and derives its name from the river Drome, by which it is traversed. It was formed out of the Valentinois, the Diois, and the Trias. It is bounded on the north by the department of the Isère;
on the west by that of the Ardeche; on the south by the departments of Vaucluse and the Lower Alps; and on the east by the departments of the Higher Alps and the Isere. The principal rivers of the department are the Drome, which has its source in the Valdrome near Serres, and falls into the Rhone near Crest; the Isere, the Roubion, and the Jabrone, which passes by Montelimart. The principal lake is called the Lac de Luc; and it and all the rivers abound with excellent fish.

The principal productions of the department are corn, vines, fruits, olive-oil and nut-oil, wool, silk, and mineral waters. Owing to the mountainous nature of the country, and the dryness of its sandy soil, the corn which it grows is not sufficient for its consumption. Wine is produced in great quantities, particularly on the banks of the Rhone, and in the districts of Die and Nyons. The most celebrated are those of L'Hermitage, Brezème, Château-neuf-du-Rhône, and Donzière. The mulberry tree thrives well, and silk-worms are reared in vast numbers, their produce amounting annually to upwards of three millions of French livres. The best pastures are at Gresse, Valdrome, and Vercors.

The trade of the department consists chiefly in cattle, butter, cheese, woollen and linen cloths, hosiery, hats, stuffs, thread, paper, and gloves. The superficial extent of the department is 69,27 square kilometres, or 350 square leagues. The forests occupy 75 or 76 hectares, or 148,000 acres, most of which belong to individuals. The contributions in the year 1803 amounted to 1,840,992 francs. The following are the leading towns in the department, with their population.

Valence is the chief town of the department. Total population 231,183. See Herbin's Statistique de la France; and Chantreux's Science de l'Histoire et de la Geographie, &c. (≠)

DRO. See Ber.

Drontheim, or Nidrosia, is a large town of Norway, in the district of Strinden, and the capital of the province of Drontheim. It is situated on a small gulf on the south side of the river Nid, from which it received the name of Nidroos, or the outlet of the Nid, and is almost wholly surrounded by that river and the sea. The town, which, excepting four houses, is wholly built of wood, has two suburbs, viz. Bakkelandet and Ladegaard, in each of which there is a church. The principal street in Drontheim, called the Munkegade, is a noble street, which extends through the whole breadth of the town to the shores of the Fjord. The buildings on both sides have a very respectable and agreeable appearance, and are in general tastefully ornamented. The beautiful island of Munkholm, crowned with its castle, rises majestically above the bay; and the view is terminated by mountains covered with snow. The principal public buildings are the town-house, the cathedral, two churches, a public school, an infirmary, a poor-house, an orphan-house, a house of correction, and a seminary for missionaries. The town-house, or Stiftsamthaus, stands in the Munkegade, and is now the residence of the chief magistrate, and the public bodies of the district. It is a large palace, which overtops the other buildings, and is visible at a distance of more than two English miles. Its style of architecture is simple and noble, but being built of wood, its ornaments have been distorted by the influence of heat and moisture, the enemies of all timber edifices. The cathedral, dedicated to St Oluf, which stands at the end of the Munkegade, was formerly a magnificent building of marble; but it was burnt down in 1530, with the exception of the choir, which still forms part of the present cathedral. This cathedral is still the finest and the largest edifice in Norway, and its great and extensive ruins enable us to form some idea of its former grandeur. The whole of the people of the north formerly resorted to it as pilgrims, to seek for the pardon of their sins on the grave of St Oluf. The town is protected by the fort of Christiansen, built in 1680, and by the castle of Munkholm, which is situated on a rock in the harbour, and which was the prison of the Danish chancellor Greiffenstien, who died in 1699.

In 1783, a school was opened at Drontheim by individuals, assisted by government, for the purpose of instructing the youth of both sexes in useful knowledge, and in the living languages. The annual payment is 10 rixdals for a boy, and five for a girl. In the year 1790, a Society of Sciences was established at Drontheim. The plan was approved and sanctioned by the king in 1787. The meetings of this society are now held in a large and beautiful stone edifice erected within these few years, and the only building of the kind in the north of Norway. The first story is occupied by the society; the high school is kept in a room below this, and the teachers inhabit the second story. The society possesses the libraries of two celebrated historians, the rector Dass and Schoening. The collection is large and excellent, and there is also a great number of manuscripts connected with the topography of the country. Counsellor Hammer, a vain collector of curiosities, bequeathed to the society, about six years ago, the whole of his collection, and a considerable sum of money; but this valuable gift, was burdened with the condition of the money being first applied in publishing the useless manuscripts of the donor. The Memoirs, which are written in Danish, contain researches in natural history, physics, and rural economy; and since the year 1784 its Transactions have been regularly published.

The port of Drontheim is frequented only by small vessels, on account of the great number of rocks at the mouth of the harbour. About 400 or 500 ships are annually employed in its trade.

In the year 1768, the amount of the exports of Drontheim was 401,507 rixdals, and of the imports 254,999. In 1790, the value of export amounted to 750,000 rixdals. In 1799, there belonged to Drontheim 63 vessels above 10 lasts. In the year 1783, the number of vessels which arrived in the harbour was 250.

The principal articles of trade are timber for masts and other purposes; copper, to the amount of 200,000 cwt. from the celebrated copper works of Roraa; iron, goat skins, furs, salt fish, herring, tallow, train oil, hides, peas, and potatoes.

The iron works at Roraa afford sustenance to nearly one-fourth of the families in Drontheim, and keep the
whole valley between Drontheim and Rorans in constant activity. An immense number of horses is employed between the two places. In winter, the copper is brought down over the snow in long rows of sledges, which carry back provisions and other necessaries. It is a remarkable circumstance that the cows are prudently fed; the dung of horses. Sometimes it is boiled in large kettles, and when mixed with a little meal, it becomes a fattening mess for cows, pigs, sheep, geese, hens and ducks, and even horses.

There are only a few manufactories in Drontheim. M. Lysholin, the commander of the town, has established an infirmary for preparing colours from the Norwegian lichens, which are collected by a number of boors in Opdalen. This gentleman also possesses a manufacture of saltpetre, and another for obtaining white kitchen and table salt from impure sea salt. In the house of correction, cloth, linen and carpets are manufactured.

In the year 1780, 48 large silver pieces, some of which were round, some square, and some triangular, were found in Drontheim. In 1789, a copper trunk was discovered, containing several coins of Frederick III. In 1805, 32 silver coins of Eric of Pomerania were found; and at a still later period, ancient silver coins, and four or five urns of a rare metal, were discovered in a sand bank. Most of these pieces of antiquity have been deposited in the Muséum at Copenhagen. In the neighbourhood of Drontheim, there are many elegant country houses. Several are pleasantly situated along the shore of the bay, on the road to Houan, towards the Fiord, and on the slope of the hills. The population of Drontheim in 1769, was 5476, in 1799, 8000; and in 1806, 8340. The position of this town, according to astronomical observation, is in E. Long. 10° 25' 25", and N. Lat. 63° 25' 50'. See Catteau's Tableau des États Danois, passim; and Van Buch's Travels through Norway and Lapland, during the years 1806, 1807, and 1808, translated by John Black, chap. v. London, 1813. (x)

DROPSY. See Medicine Index.

DROSERA, a genus of plants of the class Pentandria, and order Pentagynia. See Botany, p. 169.

DROWNING, is the extinction of life, in consequence of immersion in a fluid. It is now well known, that no animal can live without a communication with atmospheric air. Even fishes require a supply of it; for if the vessel of water in which they are kept be closely stopped, death immediately ensues. It has been likewise ascertained, that atmospheric air serves the same purposes in all animals; or, in other words, undergoes the same changes, in order to fit it for their use. These changes are effected by means of respiratory organs, with which every animal is in one shape or other furnished. Atmospheric air consists of three substances, azote or nitrogen, oxygen, and carbonic acid.

Animals accustomed to live in air perish very soon, when their respiratory organs are immersed in water; whilst the more perfect or complicated these respiratory organs are, the shorter is their duration in general, and the sooner is extinguished by such immersion. Man is capable of existing without breathing only for a very little time; and hence is soon destroyed when detained beneath the surface of the water. Most people begin to drown before they have been half a minute below it. But it is certain, that those accustomed to dive can continue a great deal longer in this state. Pearl fishers are affirmed to remain with impunity several minutes beneath the water. It is said, that some of those about Cape Comorin, in the East Indies, will keep below the surface for fifteen minutes, or even double that time. But this is probably an exaggeration.

It is still unknown to us on what the principle of life actually depends; and hence we find it often apparently lost, without its being really so. This has been denominated suspended animation, or apparent death. The term suspended animation, however, has been objected to by Dr Goodwyn, as conveying a false notion, leading mankind to believe that they are capable of re-animating, or reviscuscating, a lifeless mass, when in fact they do not more than cure a disease. "Of animal bodies," says he, "there are only two general conditions—life and death; and since by death we understand the privation of life, there can be no intermediate state between them. Of the body, in this disease, (he means apparent drowning,) we can say with propriety only, that it is alive, or that it is dead. If it were really dead, it would necessarily follow that the means which are employed to recover it must be supposed to communicate life to dead matter, which is impossible. The body therefore is alive, but with a degree of life less perfect than in the ordinary state of health; and since a difference in degree does not occasion an alteration in kind, the body must still retain that principle which is the immediate cause of all the functions that are performed in health, only it is not now excited to action; because the external concomitant circumstances which operated upon it in health are removed. These external circumstances are heat and respiration."

A certain test of death has long been, and still is, a Test of desideratum in medical science. All are now agreed death. The most complete cessation of every vital, natural, and animal function, is no sure proof that the person is absolutely dead. But it has been commonly thought that putrefaction is a certain test of this state. Mr Kite, however, has gone far to show, that even this may be fallacious. A sure indication of death, he thinks, can be drawn from the contraction of the pupils of the eyes; from one of these being more contracted than the other; from a total loss of heat, and, in the case of drowned persons, from the presence of water in the lungs. It is his opinion, that in drowning, the epiglottis completely shuts the passage to the lungs, till relaxation has taken place after absolute death. No appearance of water in the lungs was ever shown by any of the successful cases of the Humane Society, and Mr Kite immersed a kitten in a strong decoction of logwood, under a glass receiver, and kept it there for 15 or 20 minutes after all motion had ceased. He then removed it into clear water, and let it remain for a considerable time. On opening it, the lungs were filled with water, but there was no appearance of the colouring matter; a proof, he says, that the water did not enter the windpipe for at least 15 minutes after apparent death had taken place. The entire loss of irritability, or of the power of contracting in the muscular fibre, on the application of the proper stimuli, seems to constitute the true distinction between real and apparent death.

It seems to depend a good deal on circumstances that have not been accurately ascertained, how long animation may be suspended without being irrecoverably lost; or how long a person may remain in the state of apparent death, and yet recover. Instances are on record of some that have continued apparently dead for hours, nay for days, and have yet been restored to life; but no instance, well authenticated, we believe, can be produced of any person having recovered who had been
DROWNING.

more than three quarters of an hour under the surface of the water. Indeed very few have been saved who had remained nearly so long in this state. The Reports of the Humane Society abundantly prove this. Three quarters of an hour is the longest space mentioned in which any person they have been so fortunate as to recover was ascertained to have been in the water.

The phenomena of drowning have been accounted for in different ways, and it is certainly of much consequence that we should be able to discover the true theory of it; for on this will evidently depend our knowledge of the means most proper to be used for the recovery of the apparently drowned. If we knew what change it is that, on being submersed, takes place, and extinguishes altogether, or suspends the functions of life, we should have no more to do than to counteract, as far as in our power, the effects of this change; and if we could counteract them completely, we should then recover the patient.

De Haen.

De Haen, who wrote on this subject, ascribes the death of drowned persons to the repletion of the lungs with water, by which, he says, the arteries of them are compressed, and the circulation of the blood stopped. This was, no doubt, a natural enough notion for a man to form a priori. But it unfortunately happens, in most subjects of this sort, that the most obvious or likely cause, or that which generally first occurs to the mind of a philosopher, is not the true one. Subsequent experiments and observations have shewn, that scarcely any water enters the lungs in drowning.

Cullen.

Dr Cullen, in his "Letter to Lord Catoheart," attributes the death of drowned persons to the loss of animal heat, in consequence of the stoppage of respiration; and says, that dissection shews, that no water in sufficient quantity to hurt the system enters the lungs, or even the stomach; and no injury is done to the organization of those parts.

Mr John Hunter, in the 66th volume of the Philosophical Transactions, conceives, that the loss of respiration has an immediate effect in stopping the other vital functions, particularly the motion of the heart: and that if a sufficiency of life still remain, nothing more is wanting than to restore the function of respiration, for then the heart will act, and all other parts depending so immediately upon it, will instantly move along with it. He attempts to confirm this, by observing, that when a new born child has been allowed to spend too much time after the cessation of those functions peculiar to the foetus, and before the new function of breathing has commenced, the disposition to the new mode of life is thereby lost, and the child would certainly die if respiration were not artificially induced, by the introduction of air into the lungs. He also adapted a pair of double bellows to the trachea of a dog, and thereby induced artificial breathing, which he could stop or set going at pleasure. He found, that on stopping the breathing, the heart stopped, and on recommencing the breathing, the heart again moved. This process was repeated, he says, ten times on the same dog, and always with the same result. The intervals betwixt the trials being five, eight, or ten minutes.

Fothesgill.

Dr Fothergill supposes, that drowned animals are killed by the stoppage of respiration, and the consequent stagnation of a quantity of foul air in the lungs, which soon thereby acquires a sedative and deleterious power. This stagnant air, he thinks, destroys by degrees the remnant of irritability, and thus, though hitherto unnoticed, probably gives the coup de grace.

Mr Kite, in his Essay on the Recovery of the apparent

by Death, attributes the immediate cause of death in drowned persons to an apoplectic state of the brain; for by the stoppage of respiration, the blood is prevented from readily circulating through the lungs, and hence must accumulate in the venous system. But according to Dr Munro, four times as much blood passes through the brain as through any other part of the body—equally extensive. Hence there is an accumulation in the brain more than in any other part.

Dr Goodwyn, however, in his treatise, On the Connection of Life with Respiration, has rendered it very probable that no apoplectic state of the brain is induced by drowning; but that the immediate cause of death, in such cases, is the want of a proper stimulus to the heart and arteries.

The blood, we know, is the stimulus which sets these organs in motion. But blood is of two kinds, systemic and pulmonic. The former of a florid red colour, the latter dark and gruminous. The florid red colour is acquired by passing through the lungs in respiration; but when this function is stopped, the lungs can no longer impart the above quality to the blood. The heart, as every one knows, consists of two divisions, a right and a left; and these contain each an auricle and a ventricle. Now, the dark-coloured blood seems to be the proper stimulus to the right side of the heart and its vessels, and the florid blood to the left. But when the blood ceases to be rendered florid by its passage through the lungs during respiration, the left division of the heart is deprived of its proper stimulus. It will consequently stop. But when the heart stops its action, the blood is no longer sent to the brain; and its excitement being withdrawn, death, or apparent death, will ensue. In attempting, therefore, to recover any person from apparent death, our object must be to restore the motion of the heart. But this is to be accomplished by restoring respiration, as thus the proper stimulus for the left side of the heart will be prepared.

We find, moreover, that a certain degree of heat is necessary to every function of life. Consequently the heat lost by immersion in cold water, or by any other accident which produces apparent death, must be gradually attempted to be restored along with the function of respiration.

To determine the changes that take place in living animals while immersed in water, Dr Goodwyn drowned, in a large transparent bell glass, several cats, dogs, rabbits, and other smaller animals; and he describes the phenomena of drowning in the following words: "When an animal is immersed in water, its pulse becomes weak and frequent; he feels an anxiety about his breast, and struggles to relieve it. In these struggles he rises to the surface of the water, and throws out a quantity of air from his lungs. After this his anxiety increases; his pulse becomes weaker; the struggles are renewed with more violence; he rises toward the surface again; throws out more air from his lungs, and makes several efforts to inspire; and in some of these efforts, a quantity of water commonly passes into his mouth: His skin then becomes blue, particularly about the face and lips; his pulse gradually ceases; the sphincters are relaxed; he falls down without sensation, and without motion."

On dissecting drowned animals immediately after death, Dr Goodwyn observed the following appearances.

1. The external surface of the brain was darker than usual; but there was no turidity of the vessels, nor any extravasation.
2. The cavity of the lungs contained a considerable quantity of a frothy fluid, and the
DROWNING.

Pulmonary arteries and veins were entirely filled with black blood. 3. The right auricle and ventricle of the heart he found still contracting and dilating; but the left ventricle was at rest, though the auricle and sinus venous belonging to it still moved feebly. 4. The right auricle and ventricle were filled with black blood, as were also the left auricle and sinus; but the left ventricle was only about half full of the same sort of blood; and the trunks and smaller branches of the arteries proceeding from it, contained some of this black blood also.

Dr. Goodwyn's next object was to determine whether the phenomena above described are to be attributed to the effect of water entering the lungs, or only to the exclusion of atmospheric air. He drowned several animals among ink, and afterwards some in quicksilver, and in all cases found that only a very small quantity of the fluid had entered the lungs. Of four cats and four rabbits which he killed by immersion in quicksilver, five drams of the fluid was the greatest quantity he could detect in the lungs of any one of them. In some of them, none of the quicksilver had entered the lungs at all. The five drams were found in the lungs of a cat. Could this be the cause of her death? Dr. Goodwyn, to ascertain the point, fixed another cat in an erect posture. He made a small opening in the trachea, by cutting out one of the cartilaginous rings, and introduced through this opening two ounces of water into the lungs. The only symptoms were a weak pulse, and difficulty of breathing; but these soon abated, and the animal lived several hours afterwards, with no apparent inconvenience. On strangling it, two ounces and a half of water were found in the lungs. This experiment was repeated on two other cats, and the only difference in the result was, that the difficult breathing and weak pulse were somewhat more conspicuous; but in a few hours the symptoms abated, and on strangling the animals, four ounces of water were found in the lungs.

From all these experiments it is inferred, that a small quantity of water only passes into the lungs on drowning; and that this, mixing with the pulmonary mucus, causes the frothy appearance mentioned by authors; that the whole of the fluid found in the lungs is insufficient to account for the phenomena of drowning directly; and that these are produced indirectly by the exclusion of atmospheric air.

With Dr. Goodwyn we agree in considering the effect produced on the human system by immersion in water as a disease; and have no objection to the name which he has given it, viz. Melanæma. His definition is perhaps as unexceptionable as most that could be proposed. Impedita sanguinis venosi in arteriosum conversione, cæbus signis, syncope et livor cutis. Would it not, however, be better expressed thus? Syncope, et livorum cutis, ab impedita sanguinis venosi in arteriosum conversione. The usual name is Asphyxia.

Let us now proceed to state the most efficacious and approved remedies in this disease. And here it can hardly be necessary to observe, that unless the exciting cause, viz. submersion, be removed in a very short space of time, all hopes of a cure will be evidently vain. Death will have ensued.

The cure of melanæma from submersion, or the disease occasioned by remaining under water, has, since the year 1767, attracted particular attention. The numerous accidents by water which occurred in Holland, from the great abundance of water conveyance in that country, occasioned in the above year the institution of a society at Amsterdam for the recovery of drowned persons. Plans of treatment were published, and premiums offered to all who should save, or even attempt to save, a citizen from perishing by water. In the course of a few years, it was found that this society had succeeded in recovering from apparent death 150 persons. The humane example of the Dutch was soon followed by other nations.

In 1768, the magistrates of Milan and Venice issued Italy orders for the treatment of apparently drowned persons. And in the same year, a short time after, the magistrates of Hamburg extended similar assistance, not only to the drowned, but also to the strangled, the suffocated by noxious fumes, and the frozen. The Empress of Russia caused the Dutch directions to be translated into Russian; and an edict was published in Germany in 1769, by which directions and encouragement were given to attempt the recovery of all who might be in a state resembling death, provided there seemed to be a possibility of affording relief.

The magistrates of Paris adopted similar measures in 1771; and in 1773, Dr Cogan and Dr Hawes of London proposed a plan for an institution to promote the recovery of apparently drowned persons in these kingdoms. In consequence of this, the Humane Society of London was formed in 1774.

The object of this society is to publish as extensively as possible, the best methods for promoting the recovery of persons apparently dead; and at the same time to offer premiums to such as apply these methods to practice. They undertake to distribute two guineas among the first persons, not exceeding four in number, who attempt to recover any person taken out of the water for dead, within thirty miles of London, provided the person so taken out has not been more than two hours under the water, and provided the assistants persevere in using the means recommended for two hours, even though unsuccessful; but if successful, they give four guineas. This reward is to include also any other instance of sudden death, such as suffocation by noxious vapours, hanging, syncope, freezing, &c. They give any publican or other person who readily admits the body into his house, and furnishes the proper accommodations, one guinea, and secure them from the expense of burial in unsuccessful cases. And they give an honorary medal to such as furnish assistance gratis. This medal has on one side a boy in the act of blowing an extinguished torch, with the legend, Letat scintillâta forsan: and on the other, a civic wreath, with the following inscription around it: Hoc pretium civi servato tuli. A blank within the wreath is left for the person's name who may obtain the medal.

As the directions for treatment published by this society are very generally known, we do not think it necessary to insert them here at full length. But as by far the most important of them, in our opinion, are those which relate to the restoration of heat and respiration, we must beg leave to copy them.

"When the body is taken out of the water, the clothes are immediately to be stripped off, if not naked at the time of the accident. It must then be covered with two or three coats, or a blanket, or any thing answering the purpose, that can be most easily procured. The body is then to be carefully conveyed to the nearest house, with the head a little raised. In cold and damp weather, it should be laid on a bed in a room that is moderately heated, or in summer on a bed exposed to the rays of the sun, with the windows open, and not more than six persons admitted. A greater number may retard the return of life. The body is to be well dried..."
with warm cloths, and gently rubbed with flannels, sprinkled with rum, brandy, gin, or mustard. Fomentations of any of these spirits may be applied to the pit of the stomach with advantage. A warming-pan, covered with flannel, should be lightly moved up and down the back; bladders and bottles filled with hot water, heated bricks or tiles, wrapped up in flannel, should be applied to the soles of the feet, palms of the hands, and other parts of the body.

Respiration will be greatly promoted, by closing the mouth and one side, while, with the pipe of a bellows, you blow into the other with sufficient force to inflate the lungs. Another person should then press the chest gently with his hands, so as to expel the air. Thus, the natural breathing will be imitated. If the pipe be too large for the nostril, the air may be blown in at the mouth. Blowing the breath can only be recommended when bellows cannot be procured."

The Society recommends also placing the body, when wiped perfectly dry, between two healthy persons in a bed; shaking it by the legs or arms for five or six minutes at a time, several times during the first hour; covering it with warm grain, ashes, lees, &c. and the warm bath, when any of these can be procured. They likewise recommend electricity, friction, and inflating the bowels with tobacco smoke. If sighing, gasping, convulsions, or any other signs of returning life appear, they advise a tea-spoonful or two of warm water to be put into the mouth; and if the power of swallowing be returned, to give a little warm wine, or brandy and water. The person, they say, should then be put into a warm bed, if disposed to sleep, as is generally the case, should not be disturbed, and he will awake, after a short time, almost perfectly recovered.

Bleeding. Bleeding they dissuade from being ever employed in such cases, "unless by the direction of one of the medical assistants, or some other respectable gentleman of the faculty, who has paid attention to the subject of suspended animation."

We would observe here, that the injecting of tobacco smoke, electricity, and bleeding, though generally had recourse to, are all very doubtful remedies. The first and last, from their sedative powers, are much more likely to depress, than to excite the vital principle; and we have not seen nor heard of any instance well authenticated, in which electricity, or even Galvanism, has been of undoubted advantage. Indeed, we suspect that, from their over-excitement, they rather do harm than good. The grand point is, to preserve the body in as natural and easy a position as possible—to bring it by the most ready means in our power gradually and uniformly to the natural degree of heat, viz. 98°, but not above 100°; and then inflate the lungs with fresh air. These are the indispensable objects which all others are only of secondary importance; but in desperate cases, every possible remedy ought to be tried.

One thing must never be forgotten, that vigour and perseverance are of the utmost consequence in attempting the cure of this disease. No patient should be left as dead, till the remedies have been applied for three or four hours. "It is a vulgar and dangerous opinion, say the Humane Society, to suppose that persons are irrecoverable, because life does not soon make its appearance; an opinion that has consigned an immense number of the seemingly dead to the grave, who might have been restored to life by resolution and perseverance." See Goodwyn on the Connection of Life with Respiration; Kite on the Recovery of the apparently Dead; Cullen's Letter to Lord Cathcart; Hunter, Phil. Trans. vol. lxxvi.; Ellis on Respiration; and Reports of the Humane Society. (*)

DRUG-GRINDING, is a very extensive trade in London, where several powerful mills are employed in levigating and preparing the drugs used by chemists, dyers, painters, and other artists, who, till within a few years, were compelled to prepare their own materials in small quantities and they consumed them. The largest and most complete mill is at the Apothecaries' Hall, belonging to the company of apothecaries. Great advantages are found in this change of system; for preparations being now made on a large scale, bave a much greater certainty of being of an equal quality. By employing powerful machinery, the expense of labour is greatly reduced; and the loss, or waste, in different processes, bears no proportion to that which is incurred by preparations of small quantities. In levigating drugs which are of a poisonous quality, the advantages of machinery are obvious, as the machines will act without the necessity of constant attendance, and may therefore be enclosed in a close room, where the people never enter, except to supply the machine with materials, or remove what it has completed; and at these times the motion is stopped, to avoid the danger of particles being thrown up in the air.

In Plate CCXL are drawings of most of the different machines which are used in drug-grinding. It CCXL. is needless to explain the connecting wheels which put them in motion, because they are similar to other mills which are driven by the power of steam engines; though some drug-mills in the country are worked by water wheels.

Fig. 3. is a pounding machine, or mortar, to be used for coarsely breaking such materials as are too hard, and in too large masses to be reduced by other means than a heavy and sudden blow. AA is a mass of cast iron, in which are four cavitv, to form as many mortars for the reception of the drugs. The pestles BBBBB are likewise of cast iron, fixed at the lower end of wooden beams, or stampers. These are fitted to rise and fall between the cross rails aa and bb, which are fixed at the ends to the principal uprights EE, or frame of the machine. The stampers are lifted by cogs, projecting from an axis D, which is kept constantly revolving, by the power of the mill; and the cogs are arranged upon the shaft at intervals, so that they lift the stampers in succession, and by this means a constant action is kept up. As the pestles may not pulverize every particle to a fine powder, unless the operation is continued for a great length of time, this machine is only used to break the drugs coarsely, and prepare them for other machines.

A pair of rolling or edge stones are shown in Fig. 1: Rolling two of these marked AB, called the runner stones, are stones, placed edgewise upon a horizontal stone DD, called the bed. This is firmly supported upon masonry, to sustain the pressure of the other two travelling or rolling over its surface. This they are caused to do by being united to a vertical shaft E, which receives the spindle or axle of the stones AB through it in a mortise, as shown by the dotted lines. The shaft receives a rotatory motion, by means of the cog wheel F, and thus compels the runner to revolve with it; their weight being borne by the bed stone D, they crush and pulverize the materials which are spread upon it. The mortise, which admits the axle of the runner stones through the shaft,
is made pretty long, to permit the stones to rise up, when there is a considerable thickness of matter beneath them, without raising the shaft. The stones ought to grind the drugs to powder, independently of merely rolling over it, by a sort of rubbing motion which they have upon the bed. This is produced by the stones AB being cylinders of considerable breadth, and revolving round on a small circle upon the bed stone: Hence the edge of the stone which is nearest to the centre of the shaft does not describe so large a circle, or pass through so great a space as the outside edge, which is more distant from the centre; but all parts of the breadth of the runner move with the same velocity round its own axis, some parts must of course have a sort of grinding motion upon the bed stone, the outer parts of the edge of the runner moving upon the bed slower than it would move by mere contact with its surface, and the inner parts of the edge moving slower. This circumstance very materially aids the operation of the grinding, and by constantly disturbing the materials, it prevents them from consolidating into a cake. The rolling stones will levigate to an almost impalpable powder, if their action is continued long enough, and will reduce almost any substance, if the weight of the runners is proportioned to the hardness of the material they are to grind. All drug mills have several sets of these stones, of different sizes; and a great advantage in the use of them is, that they are very readily cleaned from all remains of any drug. When it is required to grind a different sort, it is done by first sweeping them clean, and then grinding them for a few minutes on dry bran, or saw-dust, which takes up every particle from the stones.

Fig. 6. is another kind of rolling stone, invented by Mr Eckhardt. In this the runner A is almost of the shape of a bottle, and is placed upon an inclined axis B, supported in a frame DEF, which revolves upon two pivots, one at A, in the centre of the bed-stone H, and the other at E, sustained by the framing of the null. To the upper part of the revolving-frame, the large cog-wheel FF is fixed, to turn the machine round. The bed stone H is hollowed, as shewn in the Figure, to adapt it to the action of the runner. This machine is well adapted for reducing drugs to an impalpable powder, by a long continued motion. The runner should then be light, that it may take less power to work it.

Fig. 4. represents a different method of levigating. AB is a cast-iron pot, shaped like a cone, with a hemispherical bottom. In this is placed an iron grind D, which is rather conical, and has a spherical end, to fit the bottom of AB. At the upper end of D, a heavy weight E is fixed. The materials to be ground are thrown into the vessel AB, in small quantities: then the grinder being caused to revolve round in the pot, rolls successively on the whole surface of the cone, and grinds upon the drugs within it, a sufficient pressure being occasioned by its own weight, aided by the mass of E. The motion is communicated by a vertical spindle F, supported in framing G, so as to be exactly in the axis of the cone AB. It is kept in constant motion by a pivot, working in the great wheel H of the mill: On the lower end of the spindle, an arm S is fixed, and has at its extremities an eye to receive the end of the grinder; therefore, when as the spindle turns, it moves the grinder round in its pot; but that it may be allowed to accommodate itself to the quantity of matter which it rolls over, the eye of S does not fix the end of the grinder, but a collar a is fitted upon a pivot, formed at the upper end thereof; and this is connected by two links, like a chain to the sides of the eye, as shewn in Fig. 5. This machine will very effectually reduce drugs to an impalpable powder, because the powder is kept in constant agitation; and therefore, every time the grinder rolls over it, the surfaces are ground, and no particle can escape. This agitation is occasioned by the lower end of the grinder underming the powder, which has been caked up against the other side of the cone, by the grinder rolling over it, and by breaking the cake it causes to fall down, as shewn in the Figure. The pot is surrounded by a table I, to prevent anything being lost; and this may be extended to any size, to contain several machines, which, being arranged in a circle, will all be actuated by the same large cog-wheel H. The fine sorts of snuff are ground in machines on this principle.

Fig. 2. is a machine used by Mr Rawlinson of Derby, to grind indigo, or other drugs, in a dry state. A, is a mortar, formed of marble, and nearly hemispherical within. The muller or grinder B, is likewise of marble, and revolves within the other, being turned by means of a crank D, formed on the spindle, which is supported vertically in the frame E. The muller is shaped something like a pear, and has in the lower part a leaf, or notch, which is of great use in keeping the materials in constant motion, whilst they are ground between the surfaces of the muller and that of the mortar. The pressure is regulated at pleasure, by the addition of weights F, on the upper end of the spindle, in addition to the weight of the muller.

Fig. 8. is a method of grinding, which is equally applicable for reducing dry powders, or for preparing them in a semi-fluid state, as colours and some drugs are prepared; for to the great object is to produce a thorough incorporation of the ingredients with the fluid. AA is a circular iron vessel, the bottom of which is adapted to receive three or four large cannon shot BB. These are made to roll round within it, by the action of arms a, which project from a vertical axis D; for as this revolves, its arms push the cannon balls round in the vessel A, and they roll over the drugs. For dry grinding, the ends of the arms are made long enough to reach down to the bottom of the vessel, and thus rake up the powder immediately after the ball has passed; a circumstance which is essential for making impalpable powders, because, when the substances are ground to a certain degree of fineness, the pressure will otherwise consolidate the powder into a cake, and prevent its further reduction. The axis D may be put in motion by wheel-work from the mill, or by a bevelled wheel d, working in the teeth of a pinion e, which is situated upon the horizontal axis f. This has a handle upon one end of it, by means of which a boy turns it; and at the other end is a fly wheel, to regulate the motion. The framing is too evident to require any explanation.

Fig. 7. is another machine, acting with cannon balls: it consists of an iron vessel AA, of a circular figure, having its interior surface cast with three semicircular channels, running all round it, for the reception of the shot BBB. The vessel is mounted upon an axis D, which is supported in framing EE, and by means of a large cog wheel F, the whole is turned round with the same motion as barrel churn. This causes the balls to roll within it, just as the balls and the powder will always occupy the bottom part, the powder is reduced as fine as possible, by the balls passing over it. The powder constantly falls down from the upper part of the vessel to the lower, and thus every part of the mass is subjected to the action of the balls. A great
D R U I D S.  

Druids were the priests of the ancient Britons, and other Celtic tribes. Respecting them, and their religion, antiquarians have indulged in many opinions, and advanced many circumstances as facts, which are totally unsupported by any authority or evidence. In this article, therefore, our principal motive and object will be to explode what is fictitious and unfounded, to correct what is erroneous, and to reduce our real and well-authenticated knowledge respecting the Druids and Druidism, to those narrow limits which truth imperiously assigns them. In the execution of this plan, we are well aware of the difficulties which lie in our way, from the intermixture and confusion of conjecture and imagination with authority and evidence, and of the violent and long-established prejudices which we must encounter and overcome.

According to most of the numerous writers who have treated on this subject, Druidism was established over many of the countries of Europe; and the Druids had anticipated the discoveries of Pythagoras, Epicurus, Archimedes, and Newton: their supposed discoveries they had made, in barbarous countries, during the darkest ages of superstition and ignorance, and while they themselves were cut off, both by their situation, and by their peculiar mode of life, from every thing that was civilized and enlightened. Our object is to prove, that the Druids were confined to very narrow limits; and that, so far from deserving the high and enthusiastic praises bestowed upon them for their learning, they were ignorant and extremely barbarous in their manners, and gloomy and cruel in their superstitions. In doing this, we shall consider the etymological derivation and meaning of the term Druid; the origin of their order and worship; the countries in which they were actually found; the ranks and orders into which they were divided; the powers, immunities, and privileges which they enjoyed; the tenets and religious opinions which they held; the deities whom they worshipped; the superstitions to which they were addicted; their modes and places of worship; the knowledge and learning which they actually possessed; and the period and causes of their extinction.

The authors of the Ancient Universal History have very justly remarked, that respecting the Druids we have only a few imperfect and incidental notices in Cesar, Diodorus Siculus, Strabo, Meli, Lucan, Tacitus, Pliny, and Ammianus Marcellinus. "These have written in so loose a manner (continue the same authors) that all their fragments put together would hardly amount to three or four pages, and these reduced to their just value, would lose one half of their bulk; whether it be that these authors but just copied one another, or only designed to say the same thing." From this statement, virtually acknowledged to be correct by one of the warmest admirers of Druidism, Colonel Vallancey, who confesses that the tenets of the Celtic religion are not as yet fully known, we may easily perceive how very limited and imperfect our real knowledge of the Druids must be, and how greatly those writers who have expatiated on the subject with so much fulness and minuteness, must have been indebted to their imagination. From the ancient authors just named, however, we must draw most, if not all, of the facts on which we can depend respecting Druidism; for the testimony of Celtic writers, whether Welsh or Irish, can never be admitted, till they are proved to have lived near the time when Druidism flourished; and even granting that they did live near this period, their accounts are too loose and exaggerated to deserve much attention or faith, especially when they are at variance with the more sober and impartial accounts of the Greek and Roman historians: on these, therefore, we shall mainly and most confidently rely, for what we shall advance on the subject of the Druids, and Druidism.

I. With respect to the etymological derivation and meaning of the word Druid, it will not detain us long, as it is rather a matter of curiosity than of real importance. The most common and popular opinion is, that Druid is derived from the Greek word δρυς, an oak; but as the name evidently was borrowed by the Greek and Roman historians from the Celtic, and was, in fact, that which they found given to the Celtic priests by the people of that nation, and not what the Greeks or Romans conferred upon them, we must look to the Celtic language for its origin and meaning. It is rather singular, that, in this language, drys has the same meaning as δρυς in Greek, both signifying an oak. As we know that the Druids paid very particular veneration to the
oak, this derivation of their name seems to be the most natural and well founded; though it might be a subject of curious, as well as interesting and useful inquiry, whether the Celtic term *drys* was derived from the Greek, or the Greek word *dryas* from the Celtic. There is, however, another Celtic derivation of the word Druid, which requires to be noticed. In the Gaelic dialect of this language, *druidh* signifies wise men; and in the more ancient and pure dialect of the Welsh, *dryg* and *dreythe* signify persons conversant in diabolical arts, or magicians. The term, in this meaning, is also found in the Irish dialect; for in the translation of the Scriptures into that language, these words occur in Exod. vii. 7; Lev. xi. 9; Neh. xiii. 3; and in Samuel, chap. i. 8, in Acts, chap. ii. ver. 1, 7, and in the Acts of the Apostles, chap. viii. ver. 9. They are, indeed, a little different in their mode of spelling, but evidently the same word. In Math. chap. ii. ver. 1, the Irish word is *druighi*; and the correspondent word in the Welsh translation is *doethian*, which differs more from the usual term than any other word applied to magicians in any of the other dialects of the Celtic, or even in the Welsh in other places. The only question therefore is, whether the Druids were more likely to receive their name from the Celtic word signifying an oak, or from that which signifies wise men, or magicians; and, upon the whole, we are disposed to accede to the former opinion, in the first place, because the term *drys* comes nearer the word Druid; and, in the second place, because the appellation given to their priests was more likely to be derived by the Celts, from what peculiarly distinguished their religion, than from what was common to it with all other religions; now, the superstitious worship of the oak was undoubtedly one of the most marked and decisive peculiarities of Druidism, and therefore it is more probable that the name Druid was derived from *drys*, than from a word that signified wisdom, a qualification which all nations, however barbarous, ascribed to their priests. After all, however, as we before remarked, this is a question of comparatively little curiosity or importance, and we shall therefore dwell no longer on it, but proceed to consider the origin of Druidism.

II. Diogenes Laertius, on the authority of Aristotle and Soteron, ranks the Druids of the Celts and Galata with the Magi of the Persians, the Chaldceans of Babylonia, and the Gymnosophists of India; and hence some authors have inferred that Druidism took its origin from one or other of these nations: but this author merely means to give it his opinion, that the Druids, and the priests and wise men of Persia, Babylonia, and India, were similar in character and privileges, and that the Druids among the Celts possessed the same rank and office as the Magi in Persia, the Chaldceans in Babylonia, and the Gymnosophists in India. From this passage in Diogenes Laertius, therefore, nothing can be inferred respecting the origin of Druidism. The next opinion which we shall notice and examine on this point, is maintained by Baxter, Horsley, Macpherson, and Pinkerton, and requires more particular investigation, both on account of the authority and support which the names of these authors may be supposed to lend it, and because it is in itself not destitute of plausibility. This opinion is stated by Mr. Pinkerton, and is strongly and emphatically: "Druidism was palpably Phoenician." This short and dogmatic sentence occurs in the 1st volume of his Inquiry into the History of Scotland, p. 17. He adverts to it also in the 62d page of his Dissertation of the Galte, where he conde-
and Phoenicians is very remote and questionable, and as there are strong presumptions against the hypothesis, arising from other circumstances, it ought to be rejected.

The next hypothesis which we shall state and examine, maintains that the Gauls were taught Druidism by Pythagoras. This, like the other, rests on the similarity between the doctrines of this philosopher and those of Druidism, and on the alleged direct evidence of the fact. With regard to the first species of proof, it may be remarked, that the points of resemblance between the religious opinions of Pythagoras and the Druids are not so numerous as those which are brought forward by the advocates of the hypothesis already rejected; but one of them, at least, is more decisive and striking. It may be doubted whether the Phoenicians actually believed in the doctrine of transmigration; but this, it is well known, was one of the peculiar tenets of Pythagoras: but, as was before observed, the transmigration held by the Druids (if they actually believed such a doctrine) was very different from the transmigration taught by Pythagoras, as we are expressly informed by Caesar: *In primis hoc volunt persuadere, non interire animas, sed ab aliis post mortem transire ad alios: atque hoc maxime ad virtutem excitari putant metu mortis neglecto.* That by this Caesar meant that they believed only in the transmigration of the soul into a human body, is evident, by the practical use which they made of their doctrine; for to believe that their souls might pass into the bodies of inferior animals, could hardly have taken away the fear of death. But, independently of this consideration, we know that the doctrine of the transmigration of the soul was by no means peculiar, either to Pythagoras or the Druids. Indeed, it is one of those religious opinions, into which mankind, in a state of ignorance, are by no means unlikely to fall. The direct evidence that Pythagoras taught his doctrines to the Druids, rests principally, if not exclusively and entirely, upon the following passage in Ammianus Marcellinus: *Speaking of the Bards, Enabaes, and Druids among the Gauls, he says: Inter hos Drudee ingeni celsiores, ut autritas Pythagorae decrevit, sodalitii adstricti consorciis, questionibus occultarum rerum altarumque eecti sunt, et despectantes humanae, promnliarat animas immortales.* In order that the full and just authority may be given to this passage, it ought to be observed, that Ammianus is here quoting from Timagenes, a Greek historian, who lived in the time of Augustus, and who, both on account of the period at which he wrote, and the researches he made, must have been a more competent authority than Ammianus himself, who flourished when Druidism was nearly if not entirely extinct. Of the researches of Timagenes respecting the Gauls, Ammianus speaks in the following terms: *Ambigentes super origine prima Gallorum scriptores veres, notitia reliquere neglii semiplenam: sed postea Timagenes et diligentia Gracae et lingua, quae diu sunt ignotara, collegit ex multiplicantibus libris; cuius fidum sequi, obscurata dimita, cedem distincte docibus et aperte.* Having thus given the passage from Ammianus Marcellinus, respecting the supposed Pythagorean origin of Druidism, all the authority and weight which it deserves, and which it does not seem to have met with when simply considered as resting on the information of that historian, we shall now proceed to examine its tendency, import, and bearing, on the point in question. In the first place, the passage may merely mean, that the Druids, in the establishment of confraternities, resembled the Pythagoreans; though it must be confessed, that, by the obvious meaning of the words, Timagenes gives it as his opinion, that the Druids acknowledged the authority of Pythagoras; but that the former interpretation, notwithstanding this, is more natural, will probably be admitted, when we reflect, that this author is completely silent respecting the Pythagorean origin of the Druidic doctrine of transmigration; a point of resemblance between the two religions, which would have much more clearly and decidedly proved the authority of the philosopher, than the establishment of confraternities—the investigation of profound and lofty subjects, and the belief in the immortality of the soul. This interpretation of the passage is further illustrated and confirmed by what Diodorus Siculus says respecting the religion of the Celts. *The opinion of Pythagoras prevails among them, that the souls of men are immortal, and live again after a certain period, entering into different bodies.* In fact, the expressions of Diodorus Siculus, *invicti, que nobis a Pythagore locae,* and of Timagenes, very nearly coincide, and may be supposed merely to mean a resemblance between the doctrines of Pythagoras and the Druids, without asserting any thing respecting the origin of the one from the other. It is also worthy of remark, that though Diodorus Siculus mentions the transmigration of souls, in connection with Pythagoras, he does not even hint, that this doctrine was borrowed by the Celts from that philosopher.

It appears to us, that it has happened to those antiquarians who have searched for the origin of Druidism among the Phoenicians, Pythagoreans, &c. as it frequently happens to men in the common occurrences of life: they have missed what they have been in search of, by directing their enquiries too profoundly, or too remotely; and the desire of finding out an origin, not obvious to common enquiries, has led them astray from the truth. On the subject of Druidism, we must either entirely reject, or we must abide, by the authority of the Greek and Roman authors; especially the latter, for the Greek historians and geographers evidently borrowed from the former every thing regarding Druidism. Where these authors express their opinion, clearly and decidedly, it is assurredly as well worthy our regard and belief, as the unfounded hypothesis of the moderns; in whom it is very unfair to disregard or reject the testimony of the ancients, on this subject, when it does not accord with their hypothesis, and to quote and rely upon it only when it serves to illustrate or strengthen them. Now, with respect to the origin of Druidism, Caesar, certainly the best authority we could have, expresses himself in terms most distinct and positive: *"Disciplina in Britannia reperta, atque in Gallia translata esse existimatur;" and as a proof of the truth of this opinion, he says: *"et nunc, qui diligentius caut vel cognoscero voluerit, pleuranque illeo, discendii causa, perficiensur.* From the expressions of Caesar, it is reasonable to conclude, that he had taken some pains to learn the general belief in Gaul, respecting the origin of Druidism; and indeed, we know that his inquiries were very minute and diligent respecting every thing connected with this country, and that what he has written concerning it may be depended upon. Here then we have the positive testimony of Caesar, that, in his time in Gaul, Druidism was supposed to have originated in Britain; and that the belief in this opinion was so prevalent and strong, that such of the Gauls as wished to learn the more secret mysteries of Druidism, went over into Britain for that purpose. We
certainly cannot look for, or expect, any testimony on this subject more direct and satisfactory than that of the people who professed Druidism; for it ought always to be recollected, that it is not the opinion of Cæsar, but the opinion entertained in Gaul, which the passage we have quoted gives; and those who contend that Cæsar was mistaken in asserting that Druidism originated in Britain, (among whom may be particularly mentioned Smith in his Gaelic Antiquities, who talks of it as a conjecture or inference of Cæsar's,) ought to be instructed that the error, if it be one, proceeded most probably from the Druids themselves. On this point, therefore, we have as clear and direct evidence as we can possibly expect; and without bewildering ourselves in conjectures respecting the source from which Druidism proceeded into Britain, we may conclude that this country was one of its most ancient, if not its original place of abode.

III. The fact that Druidism originated in Britain, if it be allowed to be sufficiently established, will remove many difficulties respecting the countries in which it prevailed; for if it were originally British, we are not justified in concluding that it is essentially and radically Celtic. "Since it must have begun to exist long after the Celts left their original settlements, it must be considered as British, not Celtic; and it would be as absurd to extend it to all the Celts, because it originated among one branch of them, as it would be to expect to find the institution of secret tribunals in the 18th century, among the Swedes as well as among the Germans, merely because they are both Gothic nations. The supposed necessary connection between Celtic population and Druidism, has prevented antiquarians from examining the question, respecting the countries in which it can actually be proved to have existed, with clearness and impartiality." (Edinburgh Review,July 1803.) There is only one objection, which, in our opinion, can be brought against the hypothesis, that it is strictly speaking British, and not essentially Celtic; if it were so, it is not easy to account for its adoption by the Celtic tribes of Gaul; for it is not likely that they would borrow a religion from the Britons. Perhaps the truth may be, that Druidism existed in its most ancient and pure state among the Celtic tribes of Britain, who, inhabiting a country to the west of Gaul, may be supposed to have been a more ancient family of Celts, than those who inhabited the latter country, and therefore resorted, as the parent stock, for the purpose of initiation in the more solemn and secret mysteries of religion. This conjecture, however, must be confessed, is at variance with the British origin of Druidism.

The two grand and leading points of enquiry respecting the countries in which Druidism actually prevailed, are, whether all the Celtic nations were Druidic, and whether it is to be found in nations not of Celtic origin? We are persuaded that there is no evidence of the existence of Druidism any where, except in Celtic Gaul, and in part of Britain; and that Mr. Pinkerton is perfectly correct in maintaining, that the Druids were "not known beyond present North Wales on the north, and the river Garonne, the bounds of the Celte in Gaul, on the south. A line drawn by the Severn in Britain, and the Severn in Gaul, forms the eastern bound, while the ocean forms the western." (Pinkerton's Enquiry, vol. i. p. 406.) On this point, as on the preceding ones, we must examine the positive authority of the Greek and Roman historians, where it is to be found, and also the presumptive evidence, drawn from other sources. Cæsar, in his account of the Druids in Gaul, states, that they were accustomed to meet annually on the borders of the territory of the Carmites, which was regarded as the middle region of Gaul. Now, in the first place, by the word Gaul, when used by itself, this author almost invariably means Celtic Gaul; and in the second place, besides his common usage of the word, it is plain that Celtic Gaul must have here been meant, since the Carmites cannot, with any propriety, be considered as Druidical, if Aquitania and Belgic Gaul were included. Besides, Cæsar, in the very commencement of his description of Gaul, informs us, that the inhabitants of the three divisions differed totally in language, institutions, and laws; and in another place he says, that the Belgic were of German origin; but from the same authority, we learn, that the Germans had no Druids. Hence, it may fairly and satisfactorily be inferred, that Druidism was confined to the Celtic division of Gaul. We shall now examine the principal ancient authorities respecting the actual site and limits of Druidism in Britain; and in the first place, it is worthy our particular notice, that "Cæsar, though he describes the Druids in Gaul so minutely," though they appear to have excited his particular attention and curiosity, "and though he mentions the received opinion, that their institutions had originated in Britain, and were, even in his time, taught there with more strictness and purity than in Gaul, yet gives not the least hint, that while he was in Britain, he had seen any Druids, or collected any information concerning them." (Edinburgh Review.) The inference is obvious and indisputable. In those parts of Britain which Cæsar visited, Druidism did not exist; nor is it likely, if it had ever flourished there, that such a circumstance would have escaped his investigation. The first, and the only authority, we believe, who mentions the existence of Druidism in Britain, is Tacitus: in his annals of the transactions of the Romans in this country, does he mention it, till they had advanced as far into Wales as the island of Anglesey. In his life of Agricola, where he has detailed all the particulars respecting Scotland, with which, it may be supposed, that general supplied him, he makes no mention of Druidism. As the superstitions and ceremonies of the Druids, by their singularity and cruelty, actually appear to have excited, in a very strong degree, the curiosity and abhorrence of the ancient writers, we may justly conclude, that their silence respecting them, is a sufficient proof that they did not exist in the countries which they describe. With respect to Germany, and other countries not generally deemed Celtic, in which, according to some antiquarians, Druidism prevailed, as there is no direct authority for this opinion, it will be more properly considered in the following observations on the presumptive evidence for the existence of this religion beyond the limits which we have prescribed for it.

The first mode by which many antiquarians endeavour to prove that Druidism prevailed over a large portion of Europe, displays a remarkable want of logical correctness. "Wherever authorities for its existence in any country, which they deem Celtic, are not to be found, they appeal to the stone monuments, which, they say, are to be discovered exclusively in countries formerly inhabited by the Celts. Or, on the other hand, assuming it as a fact, that all the Celts were Druidical, they regard these remains of antiquity, as a sufficient indication, that the country in which they are found, was formerly the seat of a Celtic population. All the parts of this argument are assumed. But even if we allow the truth of both the circumstances upon which it is founded; viz. that all the Celts were Druidical, and that
the Druids erected enormous stone temples or altars, still it by no means follows that the countries in which these exist were formerly Druidical, or even Celtic. Stone monuments, nearly similar in form, and equal in magnitude to those which are said to be most unequivocally Druidical, are found in countries, into which, according to the opinion of all antiquaries the Celts never penetrated. In many parts of the North of Germany, in the island of Zealand, and in Iceland, the stone monuments are similar in form, and seem to have been erected for the same purpose with those in Britain and France." Edin. Review.

The presumptive argument, therefore, drawn from these stone monuments, must be abandoned as untenable; but there are arguments advanced for the existence of Druidism in Germany, of a different kind, which require to be noticed and examined. The passage in Caesar has already been adverted to, in which he expressly states, that the Germans had no Druids: His words are; Germani nullum ab hominibus disserunt; nam neque Druides habent, qui rebus divinis prae- sint, neque sacrificium transit. Yet notwithstanding this clear and decisive authority, it is asserted by many writers, that Caesar was mistaken; and they charge him with ignorance or error, in consequence of what Tacitus says respecting the religion of the Druids. There can be no doubt, if this latter writer differed from Caesar on this point, that his evidence ought to outweigh that of Caesar's, since he had more and better opportunities of learning the religion and institutions of the Germans: but as the evidence of Caesar is clear and decisive, that of Tacitus ought to be equally so, before it can fairly be set up in opposition to his. But all that he says respecting the priests of the Germans, is, that they alone possessed the power of imposing silence in their public councils, and of reproving or punishing offenders; and that they were always present in their wars. In these respects, they undoubtedly resembled the Druids; but they also resembled the priests of most other savage nations: there is no proof that they resembled the Druids in what was peculiar to them. Other antiquaries endeavour to prove, that Druidism existed in Germany, by the alleged identity of the German and Celtic religions, in several of their fundamental and peculiar points. The veneration for the misletoe certainly distinguished the Druidic religion: and if it could be shewn that the same veneration was paid to it in Germany, the argument would be of considerable weight; but in the Edda, it is uniformly represented either as a contemptible or mischievous plant. It is indeed not often mentioned; but where it is, it is held forth as the instrument of evil, not as the instrument of good, as among the Celts; and the learned and ingenious translator of Mallet very appositely remarks, that it was probably held in contempt and abhorrence by the German tribes, because it had been the object of veneration among the Celts, whom they had conquered and expelled.

The most plausible argument, however, for the German veneration for the misletoe, is advanced by Keysler, who says, that the word guthyl, used by the vulgar in Upper Germany at Christmas, as they run through the streets, is the exact translation, or, to speak more correctly, the original of the omina sanans, by which, according to Pliny, the Gauls expressed the misletoe. But to this it may be replied, that, by Keysler's own account, the misletoe is not employed when these words are used; and they may most naturally be considered as referring to the birth of Christ, the literal meaning of them being bona salus, not omnia sanans. It is worthy of observation also, that Keysler mentions the reverence paid to the misletoe in Gaul and Aquitaine, where the appellation for it is gay; and certainly in this word, as existing in a Celtic country, rather than in a German word, we ought to look for the original of Pliny's omnia sanans. But even allowing that traces of veneration for the misletoe were to be found in Germany, it would by no means prove, that Druidism was anciently the religion of that country: for, as has been already remarked, as the Celts were the original inhabitants of that part of Europe, if they were Druidical, relics of that religion may be supposed to have remained among their Gothic conquerors. In many parts of England, the rural custom is still observed of hanging up a misletoe bush on Christmas eve, and trying lots, by the cracking of the leaves and berries in the fire on the twelfth night, though, as we have proved, even so far back as the invasion of the Romans, Druidism had been expelled and confined to the western part of Wales.

The next supposed point of resemblance between the Druidical and German religions, from which it is inferred that Druidism ancienly prevailed in Germany, consists in the belief of the transmigration of the soul. There is only one passage which seems to favour this resemblance, and that, if examined, will be found in fact to make strongly against the opinion that the Germans were Druidic. The passage occurs in an ancient Ode, in the Edda of Snorri Sturluson: "Sigruna is dead through sorrow and grief. It was anciently believed that men were born again, but this now is accounted an old woman's fable." The same observation may be applied to this passage, which was applied to the inference of Keysler respecting the misletoe. The Goths were disposed to treat with contempt the opinions and institutions of their vanquished and expelled foes the Celts; and to them most probably the author of the Ode refers, when he speaks of the opinion of transmigration as being ancienly held, but, as in his time, being esteemed an old woman's fable. That the Gothic tribes did not believe in the transmigration of the soul, innumerable passages from the Edda might be cited to prove, all of which describe a fixed elysium and a hell, where the valiant and the just were rewarded, and where the cowardly and the wicked suffered punishment. Besides the utter discrepancy of the religious opinions of the Druids and Germans in this point, they were totally dissimilar, as Dr Percy has shewn, in his introduction to his translation of Mallet, in many other important and essential ceremonies and doctrines. Not only therefore the direct testimony of the ancients, but all presumptive evidence, is against the hypothesis that Druidism existed in Germany.

The only other countries in which Druidism is presumed to have existed, are Ireland and Italy; but the examination of their claims will not detain us long. Respecting the existence of Druidism in Ireland, the ancient authors are wholly silent; indeed they were very little acquainted with this island. But the Irish antiquaries are loud and positive in their assertions, that their country not only had Druids, but that it was their principal and favourite abode, and that even in the time of St Patrick they were flourishing and abundant. But the authorities for these positions are little better, in point of validity and genuineness, than those which are brought forward in support of the Milesian colonization, and antediluvian dynasty of Ireland. In the introduction to the study of the history and antiquities of this country by Mr O'Halloran, we have a most charac-
teristic instance and proof of the manufacture of Irish authorities, which may well excuse us from examining laboriously or minutely their claims to Druidism. This author, indignant at the opinion expressly supported by Caesar, that the religion of Druidism was invented in Britain, without scruple alters the text of the Roman historian, and supposes that he wrote, not "disciplina in Britanniæ reperta," but "disciplina insulis Britannia reperta." This he calls clearing up and illustrat- ing the passage. Rowland, in his Mona Antiqua, sup-
poses that when the Roman general attacked the Druids in Anglesey, some of them fled over into Ireland; but for this supposition there is no authority.

With respect to Italy, the only work, as far as we know, in which it is asserted that Druidism had taken root there, is the Ancient Universal History. In the 19th volume of this work, page 78, the authors say, "The sect and religion of the Druids spread as far as Italy; for Augustus published an edict, forbidding the Romans to celebrate their mysteries." It is surprising how writers in general, so accurate and well-informed, should have fallen into this error; for, by a reference to Suetonius, it will be found, that by this edict the use of their religious ceremonies in Gaul was prohibited; and this prohibition, as well as the subsequent edicts of Tiberius and Claudius for the same purpose, seem to have been issued, in consequence of the abhorrence which the Romans felt towards the horrid usages of Druidism.

IV. The Druids were divided into several ranks and orders, respecting which Caesar informs us, that some of them were more eminent than others, and that over the whole there was one supreme head, or arch-druid. This person was chosen from among those who were most distinguished and eminent for their knowledge of the mysteries of Druidism, by a plurality of votes; and as the station brought with it considerable emolument, as well as power, and was favoured with high and pecu-

Their powers, privileges, and immunities, were
numerous and important: in fact, they seem to have possessed the supreme authority, and to have controul-
led and directed the plans and operations of the sove-
reign. According to Caesar, "no sacred rite could be performed, except a Druid were present: by means of them, as the favourites of the gods, and the depositaries of their counsels, the people offered up their thanksgivings, sacrifices, and prayers; and submitted with the most implicit veneration to all their commands." He adds, that so great was the respect paid to the character of the Druids, that when two hostile armies, inflamed with rage, with their swords drawn and their spears extended, were on the point of engaging, if the Druids interfered, they sheathed their swords, and became in-
stantly calm and peaceful. Their persons were estem-
ed sacred and inviolable; they were exempted from all taxes and military services; they exercised a civil and criminal jurisdiction; those who did not obey their de-
crees, were interdicted the sacrifices, after which, no per-
son dared to hold communication or converse with
them, so that this punishment was reckoned severer than death itself. The Druids had the privilege of wearing white garments, which all other classes were expressly forbidden to do. At their yearly court of ap-
peal, which, according to Caesar, they held in the terri-
ory of the Carnutes, they held their sittings in a consec-
ated grove; and before them all who had any private
suits or controversies appeared, and considered them-
selves obliged to submit to their decrees and sentence. In order to increase the public respect and veneration for them, they appeared to have lived in a retired man-
er, either singly or in fraternities. We have no accu-
rate information respecting the means by which they were supported; but, as the administration of justice, the practice of physic, and the mysteries of religion, were exclusively in their hands, it is reasonable to sup-
pose, that from these sources they derived consider-
able emolument. Toland, in his history of the Druids, mentions a tradition, which, if authentic, would like-
wise be the means of increasing their revenues, while it seems to be confirmed; for he explains the word senex, which, according to him, was given to them by the Lat-
in term senex.

Besides the male Druids, there were also Druidesses, who, like the former, were divided into three classes. The first lived together in sisterhoods apart from the world, having vowed perpetual virginity. They were much resorted to and venerated by the people, on ac-
count of their supposed powers of divination. Acc-
ding to some of the Druids, it was characteristic of Tiberius and Claudius for the same purpose, seem to have

V. Their powers, privileges, and immunities, were
numerous and important: in fact, they seem to have
possessed the supreme authority, and to have controul-
led and directed the plans and operations of the sove-
reign. According to Caesar, "no sacred rite could be
performed, except a Druid were present: by means of
them, as the favourites of the gods, and the deposita-
ries of their counsels, the people offered up their thanksgivings, sacrifices, and prayers; and submitted with
the most implicit veneration to all their commands." He
adds, that so great was the respect paid to the charac-
ter of the Druids, that when two hostile armies, in-
flamed with rage, with their swords drawn and their spears extended, were on the point of engaging, if the Druids interfered, they sheathed their swords, and became instantly calm and peaceful. Their persons were esteemed sacred and inviolable; they were exempted from all taxes and military services; they exercised a civil and criminal jurisdiction; those who did not obey their decrees, were interdicted the sacrifices, after which, no person dared to hold communication or converse with them, so that this punishment was reckoned severer than death itself. The Druids had the privilege of wearing white garments, which all other classes were expressly forbidden to do. At their yearly court of appeal, which, according to Caesar, they held in the territory of the Carnutes, they held their sittings in a consecrated grove; and before them all who had any private suits or controversies appeared, and considered themselves obliged to submit to their decrees and sentence. In order to increase the public respect and veneration for them, they appeared to have lived in a retired manner, either singly or in fraternities. We have no accurate information respecting the means by which they were supported; but, as the administration of justice, the practice of physic, and the mysteries of religion, were exclusively in their hands, it is reasonable to suppose, that from these sources they derived considerable emolument. Toland, in his history of the Druids, mentions a tradition, which, if authentic, would likewise be the means of increasing their revenues, while it
also further exemplifies the firm hold which they possessed over the superstitions of the people. According to this writer, the priests of the temple within whose district a family dwelt, exacted from all the members of it certain annual dues; and in order to insure the punctual and regular payment, every family was obliged, under the penalty of excommunication, to extinguish their fires on the last day of October, and to attend at the temple with their annual payment. If they paid the tribute, they received some of the sacred fire from the altar on the subsequent day; but if they failed in their payment, they were deprived of the use of fire during the whole winter. In consequence of these powers, privileges, and immunities, and of the great wealth and influence which they possessed, princes were ambitious of being admitted into their society, and many children were dedicated to the service by their parents.

VI. The Druids had two sets of religious doctrines and opinions; the one made known only to the initiated, who, on their adoption, took a solemn oath to keep this system of doctrines a profound secret. In order that these more sacred and mysterious doctrines might be still more carefully preserved from the vulgar, Pomponius Mela informs us, that they taught their disciples in the caves of the earth, or in the deepest recesses of the most gloomy and sheltered forests; and they never committed any of these doctrines to writing. Of course, respecting the nature and purport of these, we have no positive information, unless what Mela says be correct. "There is one thing which they teach their disciples, which has also been made known to the common people, in order to render them more brave and fearless; viz. that the soul is immortal, and that there is another life after the present." According to Cæsar and Dio-dorus Siculus, they also taught, as one of their esoteric doctrines, the transmigration of the soul. To this doctrine we have already had occasion to allude; and we remarked, that it differed from that of Pythagoras, in supposing that the transmigration was only from one human body to another. We also observed, at the same time, that there was some reason to doubt, whether they actually did believe in transmigration of any kind. This doubt is founded on the passage of Pomponius Mela, in which he states, that they believed in the immortality of the soul, and a future life; and that when they buried the ashes of the dead, they also buried their books of accounts, and the notes of hand of the money they had lent when alive, that they might be of service to them in the other world. This practice was certainly very incompatible with the belief, that their souls after death would pass into other bodies, and again live on the earth. Their public religious doctrines were exceedingly numerous; but they chiefly related to the most ridiculous or trifling matters. The sum of their moral doctrine, according to Diogenes Laertius, consisted in doing good, worshiping the gods, and exercising fortitude.

VII. We have no direct and clear evidence respecting the gods whom the Druids worshipped; but, from the accounts of the Celtic deities given us by the ancients, if Druidism were radically and essentially Celtic, we may suppose that the deities principally worshipped by the Druids, were Esus, afterwards called Jupiter, who, under his original character and name, was worshipped under the symbol of an oak, or even a shapeless stump of a tree; -- Mars, to whom they gave the name of Segonum, and who was regarded as their chief protector; -- Apollo, who was worshipped under the name of Rictenus, whom they regarded, not only as the sun, but as the god of medicine, and to whom they dedicated an herb called Belimunica, supposed to have been a species of henbane; -- and Mercury, whom they called Omnus, and worshipped as the god of eloquence, and of trade, and as an infernal deity.

VIII. The most horrid of the superstitious rites of the Druids consisted in human sacrifices. These, however, were offered up only on the most solemn and important occasions. The victim or victims, for there were sometimes several, were inclosed in a large figure resembling a man, formed of osier twigs; or, according to some authors, they were simply wrapped round with hay. In this state, fire was applied, and they were reduced to ashes. Pliny asserts, that they considered it as a part of their most solemn and most obligatory religion, to put men to death; and that to feed upon their dead bodies, they esteemed most wholesome. The human victims were in general selected from among the criminals; but when none of these were to be had, they did not scruple to sacrifice innocent persons. In some instances, it appears that this horrible superstition was practised, even for persons of high rank, when they were afflicted with any dangerous disease. The Druids paid particular attention to the examination of the animals which they sacrificed; and only the most perfect and beautiful were selected for this purpose. They also watched the manner in which the victim, whether human or brute, fell when it was stabbed; whether on his right or left side, or on his face; how the blood flowed at the wound, &c.; and from these circumstances, they pretended to foretell what was to happen.

These superstitions, however, were not peculiar to the Druids; but those which regarded the mistletoe and vervain, salago, and the serpent's egg, were characteristic of their religion. Respecting all these superstitions, Pliny gives us a very particular account. According to him, the Druids held nothing so sacred as the mistletoe of the oak: they believed that every thing which grew upon that tree, came from heaven. Whenever the mistletoe was discovered upon it, they went, with great ceremony and respect, to gather it. The sixth day of the moon was always chosen for this purpose. In their own language, the Druids called the mistletoe, all healing. As soon as they had prepared, under the oak, all the apparatus for sacrifice, and the banquet which they usually made, they tied, for the first time, two white bulls to it, by the horns. Then one of the priests, clothed in white, ascends the tree, and with a golden knife, cuts off the mistletoe, which is received in a white garment: after this, sacrifices are offered up. In another place he mentions the opinion of the Druids, that the mistletoe gave fertility to man and beast, and that it was a specific against all kind of poison. The same author says, that they pretended to predict future events, by means of the vervain; and that from it they extracted an ointment, which was efficacious, not only in preventing or curing all diseases, but also in conciliating friendships, and procuring the accomplishment of every wish. This plant they gathered at the commencement of the dog-days, and in a moonless night. The salago, a species of savin, they esteemed a preservative against every calamity, and the smoke of it beneficial for any complaints in the eyes. Their notions respecting the serpent's egg, (which are also detailed by Pliny,) were still more credulous and absurd. This egg was formed from the scum of a vast multitude of serpents, and secured
to the person, in whose possession it was, every thing which he could wish or desire.

1X. None of the ancient writers who describe Druidism, make any mention of temples; on the contrary, from the account which they give of the sacred grove, we may reasonably infer, that their religious rites were carried on in it alone, without the use of temples. "Tacitus, in his account of the destruction of the seat of Druidical superstition in the Isle of Anglesey, informs us, that the groves sacred to their cruel rites were cut down, as it evidently appears to have been the intention of Suetonius Paulinus to exterminate, if possible, the religion of the Druids, or at least to prevent them from continuing to offer up human victims; certainly, if temples had formed any part of their institutions, he would have destroyed them, as well as cut down their groves. No mention, however, is made of them by Tacitus; and if they did not exist in Anglesey, which is known to have been one of the most celebrated and solemn seats of Druidism, it is by no means probable that they were used in any other part of Britain." (Edin.

The notices contained in the ancient writers, on the subject of the philosophy and learning of the Druids, are neither very numerous, nor very explicit; and they prove rather their indulgence in speculative, than their advances in practical philosophy. Strabo says, that they taught the alternate dissolution of the world by fire and water, and its successive renovation: and Pomponus Mela infers, that they pretended to great knowledge of geography and astronomy; especially respecting the size and form of the earth, the motions of the planets, and their influence, as well as the influence of the stars; but from what this author adds, that by this knowledge they assumed the power of prying into futurity, we may safely infer, that their philosophy was of a very inferior and limited nature. Cicero mentions a Gaulish Druid, with whom he was personally acquainted, who professed to have a thorough knowledge of the laws of nature: and from the testimony of Caesar, it appears that they had many disquisitions concerning the heavenly bodies and their motions; but the nature or extent of their knowledge on these subjects we are utterly unacquainted with. It has been attempted to prove, that they were skilled in geometry, on the authority of Caesar; this author says, "that if any disputes arose among the Gauls, about their inheritances, or about the limits of their fields, they were referred to the decision of the Druids;" but reference was made to them, most probably, merely on account of the influence they possessed, not on account of their skill in geometry. We have seen, that whatever knowledge they possessed, or pretended to possess, in astronomy, was employed by them to preserve and strengthen the superstition of the people. Their knowledge of botany and medicine appears to have been turned to the same account. In short, if we coolly and impartially examine this subject, we shall find reason to conclude, that the Druids possessed no more philosophy or learning, than the priests of other religions in the same state of society; and that what they did possess, only served to confirm the ignorance and superstition of those whom it was their duty to have enlightened.

X. Of the philosophy and learning of the Druids, the most exaggerated and ridiculous accounts are given by those authors, who have consulted their imagination and prejudices, rather than the sober testimony of antiquity. According to them, the most wonderful and scientific discoveries of modern philosophy were known to the Druids; and their learning embraced a much wider compass than that of the sages of Greece or Rome. In the description of the Massilian grove by Lucan, just referred to, the poet mentions a report, that it was often shaken, and strangely moved; that dreadful sounds were heard from its caverns; that the yews, if thrown, or cut down, grew up again spontaneously; that the grove was sometimes in a blaze, without being consumed; and that monstrous dragons turned about the oak. It is easy to perceive in this description the fancy of the poet, adding to and embellishing those reports concerning the sacred grove, which it must have been so much the interest of the Druids to have propagatd, and which the ignorance and superstition of the people would not be indisposed to believe. Yet from this description, Mr. Smith, in his History of the Druids, prefixed to his Gaelic Antiquities, infers, that they were acquainted with the composition and use of gunpowder; "and," he adds, "if we consider the deep and long researches of these colleges of philosophers, their being possessed of the experiments of a series of ages before, and an extensive communication with other countries, we can hardly suppose the mystery of the nitrous grain could escape them," (p. 74.) Before we proceed to the more sober and rational accounts with which the ancients supply us, respecting the philosophy and learning of the Druids, we shall give one more instance of the prejudiced credulity on this topic, of those who have so largely contributed to mislead the world concerning this order of men. Diodorus Siculus, on the authority of Hecataeus, relates, that the Boreade, inhabitants of a certain Hyperborean island, little less than Sicily, lying opposite Celtiberia, saw the moon much nearer, and more distinctly, than other men. This passage is pressed into the service of the believers in the philosophy and science of the Druids; by the Boreade, it is contended, the bards were meant; the island evidently is Britain; and the British Druids were enabled to see the moon thus near and distinctly, by means of telescopes. Assuredly, these two instances (and many more might be given) bears us out in the assertion, with which we commenced this article, that on the subject of Druidism, there was great room and occasion for the most rigorous and sceptical examination.
Drunkenness.

It is stated in the book of Genesis, that Noah, soon after the flood, having manufactured wine, “drank of it, and was drunken.” This is the first instance of intoxication anywhere on record. Some have even thought that it is the first that ever occurred; and that Noah was the inventor of wine. But it is more likely, from the manner in which the sacred historian introduces the circumstance, as well as from the nature of the thing itself, that the practice of making wine was known to the antediluvians. It must, however, be confessed, that no mention is made of its use among them. But ever since the time of Noah, in all countries where fermented liquors have been known, the practice of drunkenness has been more or less prevalent.

Alcohol is the chief of the intoxicating substances; but there are others besides it which produce a similar effect. Such are opium and bangle, hemlock, nightshade, henbane, and tobacco. Nitrous oxide gas, applied for a few seconds to the lungs by means of breathing, induces a transitory sort of intoxication. Opium and bangle are used in Mahometan countries, where the laws of the prophet prohibit the use of wine. Bangle induces a sort of folly and forgetfulness, gaiety, and delirious joy. It and opium are, in truth, seducers for wine; for, in all countries, men constantly seek after something or other to rouse and exhilarate their spirits, and bring on that mental state which relieves them from every care. This disposition, however, prevails most in cold climates; for drunkenness is observed to increase in proportion as we recede from the equator. The stimulus of heat being deficient, it would appear, in cold climates, men feel more strongly the want of another stimulus, and are thus led to the excessive use of intoxicating liquors.

The ancient Germans were remarkable for their excess in drinking. And the celebrated modern traveller, Von Buch, gives us a most revolting picture of the propensity of the Laplanders to intoxication.

The state of civilization, too, has much influence on this practice. The most barbarous nations, ceteris paribus, are always the most drunken; and it is almost uniformly found, that as refinement makes progress, the habit of intoxication gradually loses ground. Not long ago in our own country, particularly in this quarter of the island, a man was deemed deficient in the duties of hospitality, if he did not make all his guests drunk before they left his table. Now, on the contrary, every man drinks or not as he pleases; and there is no compelling, as formerly, every guest to swallow the same quantity of liquor, whether he be strong or weak, healthy or delicate.

Sacred writ condemns drunkenness in the most pointed terms. It is a vice most degrading and disgraceful even in our own sex, but in the other, no language can express its deformity and abomination? The Romans put women to death, who were convicted of getting drunk. It is a crime, by our laws, punishable with 5s., of a fine, or sitting six hours in the stocks, and is accounted an aggravation of any other offence.

Drunkenness may be considered in a twofold point of view; either as a single paroxysm, or as a habit induced by a repetition of these. The paroxysm consists of two stages, that of excitement, and that of relaxation. The stage of excitement begins with an increase of heat and muscular strength, and of vigour in the circulation of the blood. The eyes sparkle, the face becomes redder, and the whole countenance is pressingly enlivened. The powers of imagination are vivid and strong; and an easy flow of spirits, with wit and humour, and a total forgetfulness of every anxious care, place the newly initiated votary of Bacchus in a paradise of pleasure. Dissipat Evius auras edaces. Love and joy, and agreeable emotions, exclusively take possession of him. The shady sides of objects are everywhere turned away, and the beauties he formerly admired are arrayed in gayer colours. All is pleasure and delight; and man is now elevated above the sphere of mortals. When arrived at this point, however, he seems to have reached the verge of cheerfulness and decency; all beyond is madness and confusion. Noise and ribaldry usurp the place of mirth, and a propensity to muscular exertion shews itself in various ways, such as dancing or wrestling, the rude squeeze, or the odd mistedulation. The song and the laugh become louder and more boisterous, and the talkers pass rapidly from one subject to another. Everything now indicates a degree of excitement totally incompatible with the mens sana in corpore sano. The weaknesses of the soul are unveiled;

Condita cum verae operis precedit Libris.

In vino veritas, says the proverb. No constitutional strength, no caution or resolution, can now sufficiently guard us against the exposure of our mental frailties.

Yet still, as Dr Trotter has finely remarked, in his Essay on the subject, “the cultivated mind is seen even in drunkenness. It commits no outrage, provokes no quarrel, and turns its ear from insult and offence. But the ignorant and iliterate man is to be shunned in proportion to his excess; it is human nature in its vilest garb, and madness in its worst form.”

Though the adage already quoted, in vino veritas, or that people often discover in drink what they would otherwise have concealed, is no doubt true in a certain sense; yet there is another sense in which it is by no means so. The sentiments a man utters, when he is intoxicated, are no sure indications of the natural dispositions of his soul. On the contrary, he is then beside himself, and in a state of delirium. He sees objects through a medium which gives them a false and unnatural appearance, and hence he seems to betray qua-
Drunkenness.

The phenomena of intoxication vary both with respect to the sort of liquor drunk, and the temperament or natural disposition of the person who drinks. Much more, however, seems to depend on the last of these circumstances than on the first. Wine, spirits of every kind, porter, strong ale, cider, perry, malm, mead, purl, koumiss, all owe their intoxicating quality to the alcohol they contain; and the liquors called liqueurs, are nothing but alcohol variously disguised.

If the inebriating liquor continue still to be applied, the high degree of excitement before described, will very soon terminate in a frightful state of relaxation. This is easily explained by a well-known law of the animal economy, that all excessive stimulation is followed by debility. A degree of paralysis or palsy now takes place over the whole frame, and the mental debility corresponds to the relaxation of the body. Objects make little impression on the senses; the passions are weakened; the understanding darkened, and the conceptions being incoherent and confused, the drunkard either remains silent, or mutters an unintelligible soliloquy. He now for the most part soon falls into a profound sleep, and sometimes an apoplectic stertor marks the oppressed state of the brain. When this is the case, the symptoms are not to be distinguished from those of true apoplexy, otherwise than by a knowledge of their remote cause. But this is sometimes unknown, and can only be conjectured from the smell of liquor in the breath, or the ejection of it from the stomach. The person is now, in vulgar phrase, said to be "dead drunk;" and this sometimes turns out to be literally true, for real apoplexy, palsy, or convulsions, at times supervene, and conclude the scene. In a person dead drunk, the only signs of life are the stertorous or snoring respiration, with the pulse full and slow; and the warmth of the body still remaining. The usual way, however, in which the drunken paroxysm goes off, is by a few hours sleep, during which the alcoholic stimulus is either evacuated by perspiration, vomiting, or urine, or is somehow neutralized by the action of the system. The drunkard then awakes with a feeling of low spirits; of nausea and loathing of food, of languor and head-nach; seldom with any recollection of what has passed.

When death has been the consequence of the drunken paroxysm, dissection has shown the brain to be exactly as it is found in true apoplexy. Morgagni has related several such cases.

The power of resisting cold and contagion, and a want of sensibility to pain, has been often observed to be surprisingly great in persons intoxicated. In this respect they resemble maniacs.

It is, however, during the first stage of the drunken paroxysm only that this resistance to cold takes place; and the same may be said with respect to contagion. This we know to be always strongly resisted by that firmness and resolution of mind which necessarily accompanies a vigorous circulation of the blood.

The insensibility of the inebriate to pain, is strikingly remarkable. Drunk people fall off their own feet and off their horses, with greatly less injury than others usually do. Sailors, says Dr Trotter, whose heedless revels expose them to more disasters than other men, frequently receive the most frightful wounds and bruises, without the smallest signs of feeling, and without any recollection afterwards of the manner in which they were inflicted.

The symptoms we have hitherto described are those which usually appear in persons not addicted to a habit of drinking; but with such as are, they vary considerably. One great point of difference is, that the pleasant feelings at the commencement of the drunken paroxysm are by no means so strong in them. For by frequent repetition, the relish for wine is blunted; and while the desire for the application of the stimulus is augmented, the pleasure arising from it is diminished. And this is what distinguishes a temperate man from a sot.

The effects of inebriating liquors will be very different at different times. They will vary with the habit of intoxication, the fulness or emptiness of the stomach, the time of the day, the heat of the climate, the season of the year, the temperature of the room, and in short with whatever tends to vary the excitability of the system. Every person knows, that less liquor will produce intoxication in the forenoon than after dinner; and we learn from Captain Bligh's narrative, that when he and his companions in an open boat in their passage to Timor, were, from a scarcity of provisions, reduced to a state of almost continued fasting, a single tea-spoonful of rum produced inebriation. This state of the system has been called accumulated excitability. But in typhus fever it seems to be in a state directly opposite; for then two or even three bottles of wine will sometimes be used in the four-and-twenty hours, and that too by delicate females, without inconvenience.

When the stimulus of fermented liquors is frequently resorted to, the efficiency of it is gradually diminished; and to produce the same effect on the system, a larger quantity of the same sort of liquor, or else a similar quantity of a stronger sort, must be applied. For it is a law of the animal economy, that all stimuli, whether mental or corporeal, lose their effect by repetition. We may hence account for the charm of novelty in our gratifications, and how it comes to pass, that men of pleasure, who have exhausted every source of enjoyment by frequent repetition, are the most miserable of mortals, and exclaim in the bitterness of their hearts, that "all is vanity." They are seized by an ennui which nothing can relieve; and go about seeking gratification, without finding it.

Some of the strongest symptoms of the drunken habit, are a neglect of dress and cleanliness; a slovenly, sallow, or bloated appearance; and not unfrequently a sort of convulsive or paralytic motion in the gait, well known to most people. When any person once begins to shew these symptoms, we may fairly put him down as nearly in a hopeless state. Gout, and consumption, and diabetes, and water in the head, have perhaps been sometimes cured, though long and justly reckoned oppressa medicina; but the habit of intoxication exceeds even these diseases in obstinacy. It may indeed almost be said to be a "country from whose bourne no traveller returns." One perhaps in a thousand may escape the devouring gulf. Nowhere is the elegant allusion of the Jewish prophet more completely verified than here; "Can the Ethiopian change his skin, or the leopard his spots?" The habit of drunkenness is scarcely ever got the better of.

"It is not uncommon to hear people say that they have
known many hard drinkers live to a great age; and that if spirituous liquors be a poison, as physicians and moralists tell them that they are, they must indeed be a very slow poison, for such a person of their acquaintance has now attained his 80th year, for example, and yet has drunk hard all his life. This, however, is a very gross and most pernicious deception, much resembling the lists of remarkable cures said to be performed by quacks. You hear of those that have survived their prescriptions, but nothing of those who have perished. And from the nature of the thing itself, though we had nothing else to go upon, we might conclude even a priori, that such excess of stimulation must wear out the system, and hasten its decay. But we have other evidence,—we have the test of experience to shew that it actually does so, and that long-lived drunkards are only exceptions to a general rule. "On comparing," says Dr Willan in his Report of the Diseases of London, "my own observations with the bills of mortality, I am convinced, that considerably more than one-eighth of all the deaths that take place in persons above twenty years old, happen prematurely through excess in drinking spirits."

But it is not drinking always to the point of intoxication that is necessary to constitute intemperance. The health, as well as the mental faculties, may be ruined by a regular course of what some consider as sober drinking. Half a bottle or more of wine, for example, taken every day, is thought by many to do no harm. But perhaps the degree of constant excitement thus kept up, is more trying to the system, and ultimately more pernicious, than getting completely drunk would be at longer intervals. Dr Gregory, in his Lectures, gives it as his opinion, that of the two, a man had better drink no wine during the month, and then make himself completely drunk at the end of it, than swallow half a bottle of port every day, though he may never seem to be thereby intoxicated at all. Because in the former case the system has time to recover itself from the shock given it before it receives another; whereas in the latter case, it is constantly as it were kept upon the stretch.

Wine, however, and other alcoholic liquors, we do not prescribe altogether. It is only their abuse that we condemn. A certain dose, if we may so speak, of any of them, will frequently be attended with good effects, or will at least do no harm. But then it belongs to the prudence and judgment of a wise man, to regulate the quantity he uses, as much as it belongs to him to regulate the quantity of common food he takes; for by excessive indulgence in this as well as in the other, he will most certainly impair his health. It is impossible to give a general rule for the quantity of wine or spirits that may be safely employed in a given time. But we think that three or four glasses of wine, or one of spirits much diluted with water, daily, is as much as can be taken by most men without producing more or less injury to the system. We do not deny that many persons can use a great deal more than this without its bad effects being for a long while sensibly felt. We only say, that for the most part it will do rather harm than good. The quantity of spirituous liquor that can be swallowed undiluted at one time without endangering life, is not very great. But the writer of this article once knew a countryman of twenty-two years of age, who, for a wager of one guinea, swallowed at two draughts a quart bottle of proof spirit rum, and after he had done so, walked a mile home to his own house.

Vomiting then came on, and he recovered after a prettily severe shock to his constitution.

"Wine is an excellent remedy for some diseases; but why take physic when in good health? In the latter stage of typhus it is the best remedy we know; and as old age is considered by many as a disease also, it is (we do not say, a remedy) but a palliative for it too. No person, however, Dr Trotter thinks, if in good health, "can need wine till he be forty. He may then begin with two glasses a day; at fifty he may add two more; and at sixty he may go the length of six, but not to exceed that quantity, though he should live to an hundred." Such is a good rule for the abstemious, who have not early indulged in wine. Others may require more.

Not only poets, but physicians even of no less name than Haller and Hoffmann, have represented wine as favourable to mental vigour. This, however, is certainly a mistake. All those persons who have made the greatest improvements in works of genius, have been of sober and temperate habits.

We shall here put down a few of the most curious instances of mental hallucination, that have been ascertained to proceed from excess in drinking. Atheneus tells us, that a drunken crew at Agrigentum in Sicily, hearing the winds roar on the house in which they happened to be, became so fully persuaded that they were on board a ship, and in danger of suffering shipwreck, that they threw all the furniture out of the windows, under the idea that they were lightening the ship. A drunken man has been known to whip a post, because it would not move out of his way; and an old gentleman of eighty, when intoxicated, once took a lamp-post for a lady, and addressed her in all the impassioned and flattering language of love. "I have myself," says Junius, in his Character of Drunkards, "seen a scholar and a witty man, somewhat gone in drink, take up a sand barrel instead of a bowl of beer, in a grocer's shop, and having said, 'Here, cousin, to all our friends; hold it to his mouth till a great part of the sand ran in between his teeth.' He mentions another drunken man who was stopped in his progress by the shadow of a sign-post, which he thought it impossible to get over; and a third, who, seeing the moon shine through a small hole in the wall, attempted to light his candle at it. Another, he says, fell down drunk in Fleet Street, and when people offered to help him up, he exclaimed, 'What, can't I be quiet in my own room?'

Alcohol not only intoxicates, it also acts chemically on the human body. It constrains the dead animal solid, and retards putrefaction. It coagulates the serum of drinking the blood, and most of the animal fluids, and undoubtedly, in some measure, deoxygenates the blood.

Saussure junior has shown, that alcohol contains about 15 per cent. of hydrogen. Now that this gas, in the inebriate, is sent off in a disengaged state from the lungs, is evident from the factor of the breath. Indeed, it is sometimes so pure, that the breath of the drunk drinker will inflame on the approach of a candle.

It is well known that there are on record many cases of the actual combustion of the human body, produced by the long and immoderate use of alcohol. These have been collected in a curious memoir by Pierre Aime Lair in the Journal de Physique, Pluviocée, year 8th.

The reader who wishes for more information on this strange subject, we must beg leave to refer to the above document. It has been copied by Dr Trotter into his
Drunkenness.

interesting Essay on Drunkenness. It is remarkable, as has been observed by Pierre Aime Lair, that this sort of combustion occurred only in women far advanced in life.

The diseases brought on by drunkenness are so many, that we can do nothing more than barely enumerate them here. For their history and manner of production, we must again refer to Dr Trotter. He divides them into two sections;—those which appear during the drunken paroxysm, and those which are induced by the continued habit of drinking. His first section contains apoplexy, epilepsy, hysteria, convulsions, onerodynia. His second, phrenitis, rheumatism, pleurisy, gastritis, enteritis, ophthalmia, carbuncles, goutarosce, hepatitis or diseased liver, podagra or gout, scirrhous of the bowels, icterus or jaundice, dyspepsia or indigestion, hydrops or dropsy, tabes, atrophy or emaciation of the body, syncope, palpitation, diabetes or excessive discharge of urine, locked jaw, palsy, ulcers, madness and idiocy, melancholy, impotency, premature old age. A most formidable catalogue certainly, but all of which are shewn by him to be often induced by a too free use of vinous liquors. Dr Gregory has observed, that dram drinkers are peculiarly predisposed to gangrene or mortification.

In attempting to prevent or cure the drunken habit, venienti occurrite morbo, is a most invaluable maxim. Let every individual who has the least regard for his safety beware. Scarcely any thing can equal the danger of his once giving way. If he indulges ever so little the desire he may feel for the stimulus of vinous liquors, he is in the utmost peril of being ultimately undone. The enemy once admitted, will scarcely ever be afterwards expelled. Many a drunkard has the author of this article had occasion to observe; and among all the number who have fallen under his notice, he does not remember to have seen one of them in whom the habit was cured. Some, from external constraint, or the powerful influence of the fear of a superior, have been induced to remain sober for a considerable time, for months perhaps together; but universally did they relapse when the restraining cause ceased to operate. He once knew a gentleman of good family, so lost by the habit of ebriety, that he has seen him cry like a child when the lady of the house refused to give him a glass of whisky in the forenoon. Wine he little valued, as the sensibility of the nerves of his palate and stomach were so much blunted by excessive stimulation, that he could hardly distinguish it from water. If denied pocket money to procure whisky, he constantly pawned his shirts or other parts of dress whenever he had an opportunity. He died miserably at the age of 51, so dropatical, that for the last six weeks of his life he could not be removed from the sitting posture.

The cure of a confirmed habit of drunkenness, is, as we already said, hardly to be expected. It is so much a disease of the mind, that "herein the patient must," in a great degree, "minister to himself." But then so debased is the mind, so enfeebled, so enslaved, that it is altogether incapable of making the necessary efforts. It becomes the willing slave and victim of the foe.

Withdrew at once.

It is a question with some, whether, in the attempt to cure habitual drunkenness, it would be safe, even if the patient were willing, to leave off the use of wine or spirits all at once. Dr Trotter has no doubts on this subject. He does not think that there is any soundness in the reasoning, which would prove that it is dangerous to withdraw all at once the accustomed stimulus of alcohol. We daily perceive in all parts of the world, men who, by profligacy and hard drinking, have brought themselves to a jail; yet if we consult the records of the prison, we shall not find that any of these habitual drunkards died by being forced all at once to commence a sober course of life. "As far, (continues the Doctor) as my experience of mankind enables me to decide, I must give it as my opinion, that there is no safety in trusting the habitual inebriate with any limited portion of liquor. Wherever I have seen the drunkard effectually reformed, he has at once abandoned his potation." We think this very probable indeed, but at the same time are of opinion, that a habitual drunkard has been very seldom seen effectually reformed.

DRUSES, or Denovo, the name of a free and warlike tribe, who inhabit Mount Libanus. They attracted the attention of Europe about the end of the 16th century, in consequence of the visit of one of their princes to Italy. At this time there was much speculation concerning their origin, the meaning and derivation of their name, and the nature of their religion; the prevalent, but unfounded, opinion being that, as they professed a species of Christianity, they were the descendants of the Crusaders; and the similarity of their name to that of Dreux, in France, gave rise to the system of a pretended colony of French, who, under a Count de Dreux, had established a colony near Mount Libanus. At length M. Mitchell, Dragoman of France, at Saide, of which place he was a native, discovered the real derivation of the name of Druses; it takes its origin from the founder of the sect of Mohammed Ben Ismael, who was surnamed El Dorzis; but it is to Messrs Volney and Niehrler that we are indebted for the history of this tribe, and an account of their government, religion, manners, &c.

That they were not the descendants of the Crusaders, is evident from the circumstance that they are mentioned in the Itinerary of Bergamum of Tudelas, who travelled long before the time of the Crusades; their origin, indeed, goes back as far as the end of the 10th century. At this period Hachem, the third of the Fatimite caliphs, sat on the throne of Egypt: his reign was a wild mixture of vice and folly; at last he carried his madness so far as to wish to pass for God himself. In this impious pretension he was supported by an impostor, named Mohammed Ben Ismael, who came from Egypt. Their reign, however, was short, the false prophet being slain in a tumult, almost in the arms of the caliph, and the latter being assassinated by the emissaries of his sister. The proselytes whom they had made took refuge in the mountain of Libanus, and soon formed a independent society. The Turks, for a long time, paid no attention to this new state, either overlooking it by reason of its insignificance, or being occupied with affairs of greater moment. The Druses, emboldened by this inattention, frequently came down from the mountains, and fell on the neighbouring country. At length, in 1588, the Sultan Amurath III. finding that his pachas in vain endeavoured to repress their outrages, resolved to reduce them; and his general, Ibrahim Pacha, completely succeeded. On their conquest, he changed their constitution, allowing them only one chief, instead of a multitude of Shaiks, or lords. This measure, however, rendered them,
D R U

Druses.

in fact, more formidable to the Turks in future, since it placed the whole power of the tribe in the hands of one man; their hostilities, indeed, were secret, but they were carried on with great activity, and generally with success. Their power was at its greatest height about the beginning of the 17th century. At this time Emir Fakereideh, commonly called Fakarideh, was their chief. He ingratiated himself into the confidence and favour of the Turkish government, by making war upon the Arabs, who infested the plain of Balbec. Of this district, as well as of several adjoining districts, he made himself master, till at length the Turkish government began to be alarmed at his rapid and extensive progress, and made preparations to crush him; he did not, however, think it prudent to await the attack; but having previously formed connections in Italy, he resolved to go thither himself, either for the purpose of refuge till the storm was over, or in the hopes of gaining assistance, which might enable him to repel it. It was at this period that the hypothesis concerning the origin of the Druses from the Crusaders took its rise; and Fakarideh finding it favourable to his hospitable reception in Italy, rather countenanced it. After a stay of nine years in this country, the Turks having been repulsed by his son Ali, he returned to resume his government; but attempting to introduce the luxuries of Europe, the Druses became dissatisfied; the Turks invaded the country, to whom in a short time he was betrayed and delivered up; he was carried to Constantinople, and strangled about the year 1631. Nothing important occurs in their history from this time till the year 1770, when they suffered considerably in consequence of having been prevailed upon to take part in the war between Ali Bey and the Emir Yousef.

The great majority of the Druses have in fact no religion, being equally indifferent to Christianity and Mahometanism. They do not consider it necessary to fast or pray, to practice circumcision, or to make the pilgrimage to Mecca. They eat pork, drink wine, and consider marriage between brothers and sisters as lawful. But there is one class of men who profess very singular religious opinions, and whose religious customs are very peculiar. There are various orders of this class: the highest requires celibacy. They consider themselves so pre-eminently pure, that if one of their order eat off their plate, or drink out of their cup, they break them. On this account, vessels with a kind of coo, which may be drank out of without touching them with the lips, are very common among the Druses. They have some sacred books, filled with mystic jargon, but which also treat of another life, and describe several degrees of perfection to which they are to arrive by successive trials. The whole tribe of the Druses are divided into two classes, the common people, and the Shaiks or the descendants of princes: all cultivate the land. The common produce is the mulberry and vine; in some places, tobacco, cotton, and grain are grown. When their crop of silk is over in Lebanon, a great many of them leave the mountains, and go into the plains to assist in getting in the harvest. Their chief, called Haksam, possesses both the highest civil and military powers. The dignity is transmitted either from father to son, or from one brother to another. On failure of the male line, the government devolves on him who, to the greatest number of suffrages, can add the protection or approbation of the Turks. The Pacha is paid a certain portion of the tributes; the rest belongs to the Hachem. This tribute is imposed on the different productions of the country: the shawks and emirs are not exempted from it. No troops are kept, either by the chief or the emirs. When hostilities commence, every person is called upon to march: he brings along with him a bag of flour, a musket, some bullets, and powder. Such an army cannot be formidable; they are all on foot, except the shawks and emirs: cavalry, however, from the nature of the country, are of little service. The number of men able to bear arms is about 40,000, which supposes a population of 120,000; and as the whole country contains only 110 square leagues, there must be 1090 persons on every league. This excessive population is supposed to arise from the freedom which they enjoy, their great frugality, and the emigration of Christian families from the Turkish provinces. The character of the Druses is elevated, energetic, and active; their activity, indeed, partakes of restlessness; and they are brave, even to temerity. These features in their character evidently proceed from their enjoying a considerable share of civil and personal freedom, and from the comparison which they naturally and proudly make between their own condition and that of their neighbours. Like most barbarous nations that are bold and daring, they are strongly averse to the forgiveness of injuries; no people are more nice with respect to the point of honour, or the sense of insult: hence, in their manners, they are scrupulously attentive, and even polite to a degree not usual among peasants. Their notions of the obligation and extent of hospitality are as delicate; every supplicant or passenger is entertained with lodging and food; and when they have once contracted with their guest the sacred engagement of bread and salt, nothing can induce or compel them to violate it. They are permitted by their laws, their religion, or the custom of their nation, to marry several wives; but of this permission few avail themselves, except the emirs. They live in general a very retired life, the men cultivating their lands, and the women making the bread, roasting the coffee, and performing all domestic duties. In the evening, the men usually assemble either in the house or area of the chief of the village or family; where, seated in a circle, with their legs crossed, pipes in their mouths, and pintards in their belts, they converse about their respective labours and employments, the amount of taxes, the conduct of the emir, &c. &c. The only education, (if education it can be called), which their children receive, is derived from listening to these evening discourses of their fathers; they are never taught to read. The language of the Druses is very pure Arabic. See Niebuhr's Voyages, tom. ii. p. 351-7; Volney's Travels, tom. ii. chap. 21. (w. s.)

D Y R A S, a genus of plants of the class Ic sandria, and order Polygynia. See Botany, p. 328.

D R Y D E N, John, the Poet, was born in the parish of Old Winkle, All Saints, on or about the 9th of August 1632. His family had been distinguished for puritanism, and his father had acted as a justice of peace during the usurpation. Our poet is supposed to have received the rudiments of his education at Tichmarsh, and was admitted a king's scholar at Westminster under the tuition of the celebrated Dr Busby. Having obtained a Westminster scholarship, he was
admitted of King's College, Cambridge, on the 11th of May 1650, and after three years standing, took the degree of bachelor of arts, but never rose to that of master. From the university he was called away for a time by his father's death in 1654, to take possession of his inheritance, consisting of two-thirds of a small estate near Blakesley in Northamptonshire, worth in all about sixty pounds a year. The other third part of the small property was bequeathed to his mother during her life, and reverted to Dryden at her death. After his leaving the university, his first patrons were his kinsmen, Sir Gilbert Pickering and Sir John Dryden, both zealous puritans, and adherents of the commonwealth—and, consistently with this patronage, he wrote his Elegy on the Death of the Protector. But at the restoration, being now in his 30th year, without an adequate provision or regular profession, and without the smallest hopes of any promotion, by the aid of his puritanical friends, he seems to have lost no time in adapting his praises and principles to the changed aspect of affairs. He accordingly testified his joy at the restoration of Charles, by his poem, entitled "Astrea Redux," and added another, entitled, "A Panegyric on his Sacred Majesty." At this commencement of his literary career, he was connected and probably lodged with Herringman the bookseller, near the New Exchange, and wrote prefaces and occasional pieces for him. Neither panegyrics nor occasional verses were, however, adequate resources for one who had now to subsist principally by his pen; and as the restoration had thrown open the long shut theatres, he betook himself to writing for the stage. His first piece, "The Wild Gallant," a comedy, came out in 1663, without success. In 1664, he brought out the "Rival Ladies," which was more fortunate, and he prefixed to it his "Essay on Dramatic Rhyme;" and, in the same year, he joined with Sir Robert Howard in "The Indian Queen," to which there is all reason to suppose that he contributed the most poetical part of the verses. The poet's connexion and friendship with Sir Robert Howard, introduced him to the family of the Earl of Berkshire, father to his friend; and in the course of this intimacy, having gained the affections of the Lady Elizabeth Howard, the Earl's eldest daughter, he soon afterwards married her. "The Indian Queen," having been succeeded by "Achitophel," was succeeded in the same year by his "Indian Emperor," which had a still more favourable reception. For some months after the dreadful fire in London in 1666, the theatres were shut, and he appears to have employed his leisure in producing his "Amo Minamitabils," which was published the following year; the first poem not dramatic in which the power of his imagination came considerably forth. Nearly coeval with this was his prose Essay on Dramatic Poetry, in which he vindicates the drama as the highest species of poetry, and rhyme as the most becoming dress in which it can be arrayed. The essay is conducted in the form of a dialogue, in which Crites, the champion of blank verse, was meant to designate his brother-in-law, Sir Robert Howard. The cause of rhyming plays, Dryden had already espoused in his introduction to the "Rival Ladies." Sir Robert had made a direct answer to those arguments, and Dryden, in his dramatic essay, retaliates with some severity. The other restated his opinion in the preface to one of his plays, called "The Duke of Lerna," published in 1668, and Dryden retorted in a defence of the Essay on Dramatic Poetry. The acrimony produced by this dispute between the poet and the baronet, certainly occasioned a breach of their personal friendship; but the quarrel fortunately did not prove irreconcilable. Confiding in the fertility of his pen, our poet now undertook to write, for the king's theatre, no less than three plays in the course of the year. In consideration of this engagement, he was admitted to hold one share and a quarter in the profits of the house, which was stated by the managers to have produced him three or four hundred pounds communis annis. He seems, however, to have felt himself, as we might well expect, incapable of performing the task he had undertaken, for the average number of his pieces did not exceed one half of that number. The players, however, though they complained of his dawdling, were still anxious to retain him.

In the year 1667, was represented his "Maiden Queen," a tragi-comedy, which was so far favoured by Charles II. that he gave it the title of his play. It was followed (in 1668) by "The Tenacest," an alteration from Shakespeare's play of the same name, in which he co-operated with Sir William Davenant. His next play, "Sir Martin Marall," which was originally a translation, by the Duke of Newcastle, from Molière's "Etourdi," was brought on the stage for his own benefit, and, aided by the excellent performance of the comedian Nokes, was played thirty times at the theatre in Lincoln's Inn. "An Evening's Love, or the Mock Astrologer," was his next composition: it is an imitation of "Le Feint Astrologue" of Thomas Corneille, a piece levelled at the prevailing folly of belief in astrology—a belief, however, from which the mind of Dryden was not itself exempt. "The Royal Martyr," was acted in 1668, and printed in 1670. It is in every respect an heroic tragedy, and had a large share of the applause with which those pieces were then received. It was at this period, also, that he produced his first and second parts of his "Conquest of Granada," written, says Dr. Johnson, with a seeming determination to glut the public with dramatic wonders—to exhibit, in its highest elevation, a theatrical meteor of incredible love and impossible valour, and to leave no room for a weaker flight to the extravagance of postscript. They were acted in 1669 and 1670 with unbounded applause. While Dryden was thus generally known for poetry, the advancement of his fortune bore no equal progress to the splendour of his literary fame. Something, however, was done to assist it. The office of royal historiographer had become vacant in 1666, by the decease of James Howell; and, in 1668, the death of Davenant opened the situation of poet laureat. These two offices, with a salary of £200 paid quarterly, and the annual butt of Canary, were conferred upon Dryden on the 18th of August 1676; the grant bearing a retrospect of two years to the demise of Davenant. Dryden was now in the zenith of his reputation as a writer of rhyming, or what was called heroic tragedy. Good taste ought to have been the first antagonist of this bombastic species of poetry; but it was reserved for the second rate talents of mimickry and parody to turn it into contempt. Villiers, Duke of Buckingham, in conjunction with other wits, wrote, in 1671, the celebrated burlesque drama, entitled the "Rehearsal," of which Dryden, under the title of Bayes, was made the hero. Dryden did not answer the "Rehearsal," but he took a subsequent vengeance on Buckingham, when, in "Absalom and Achitophel," he delineated the character of Zimri. His "Marriage a la Mode," a comedy,
Dryden appeared in 1675, dedicated to the Earl of Rochester, whom he acknowledges not only as the defender of his poetry, but the promoter of his fortune. This was the same infamous Rochester, who, on supposing Dryden to be the author of a satire really written by Lord Mulgrave, was base enough to hire ruffians, to way lay and beat him with bludgeons. His play of "Assignation, or Love in a Nunnery," bears the same date with publication, and was driven off the stage. "Ambysonia," a tissue of verse and prose dialogue, written to influence the nation against the Dutch, was not worthy of a better fate. Without entering individually on the notice of all his plays, we shall only remark, that, in 1675, "Aureng Zebe" was the last of his rhyming ones. Experience, and the study of Shakespeare, had taught him, even during the composition of his pieces, that the fierce passions of the stage were unfit for the fetters of rhyme,—an appendage as inappropriate to the theatrical poetry, that would develop strong, simple, and naked nature, as a load of close and ornate drapery to the sculpture of the human form. Still he had hopes of employing rhyme in a province of poetry, where he conceived that he could use it, with all its splendour. He projected an epic poem on the subject, either of Arthur, or the Black Prince, and besought his patron Mulgrave to use his influence with his Majesty, that he might be insured of subsistence while he should compose it. Mulgrave gave the poet an opportunity of conversing on the project with Charles; but from the king he had only fair words. The court, however, required a literary champion to oppose the popular strength of Monmouth and the Whigs, through the medium of the press; and Dryden was selected as laurent, to fight the battles of Toryism with keenest, though lighter, weapons than epic poetry. For this purpose, came forth his "Absalom and Achitophel," a satire not new indeed in its plan of scripture parallel, but in strength and fineness of execution altogether unprecedented. The joy of the Whigs on the acquittal of Shaftesbury, was said to be suggested by Charles himself, as the subject of his next satire, which took its name from the medal worn by the opposers of court politics on that occasion. Among the host of inferior rhymers who answered the medal with abundant abuse of Dryden, Og and Doeg, or Shadwell and Settle, received a ridiculous immortality from his castigation; the former, in Macfleuenoe, the prototype of the Dunciad; the latter, in the second part of "Absalom and Achitophel." These were followed, in 1689, by his Religio Laici, a poetical defence of the English church against the sectaries. It has been urged, with some appearance of reason, by those who have accounted for Dryden's subsequent change to the Roman Catholic faith, on the score of principle, that he wrote the Religio Laici in a state of scepticism concerning revealed religion; not of hard and confirmed scepticism, but of that gentler sort which is accompanied with such a willingness to believe, as extrinsic circumstances might afterwards lead to the opposite extreme of credulity. It is well when scepticism can be thus cured; but the idea of Dryden sitting down half a sceptic to convert others, places him in no very venerable light as a teacher of religion. The drama of "the Duke of Guise," written in conjunction with Lee, in which a parallel was plainly exhibited between the Leaguers of France and the party of Monmouth, was another favour which he conferred on the ruling powers. About the same time, the king's express command engaged him in translating Maimburg's History of the League, the dedication of which to Charles is allowed to savour strongly of political ferocity. The king is exhorted to lay aside his forgiving disposition, and to treat the conspirators as Hereules dealt with Antaeus—"they must be hoisted from their mother earth, and strangled in the air." This pious exhortation was given after the reign of Charles had filled Scotland with tortures and legal massacres; after he had trampled on the liberties of England, and robbed her cities of their charters, at the time when Jeffries polluted the bench; and in the year (1683,) that Algernon Sidney died on the scaffold. It is much to be hoped that Dryden approached his political tasks with a little of that scepticism which is supposed to have attended his first religious lucubration. For all these services, it appears that he received only one donation of 100 broad pieces; and a deplorable memorial of his poverty still remains in one of his letters to Hyde, Earl of Rochester, imploring in vain for some permanent subsistence; deplorable we may call such a memorial, for the effects of his subserviency to bad principles passed away with the cause which he supported, while the benefits which he conferred on literature still remain. Under the following reign he became a Roman Catholic. King James added L.100 to his pension, and Dryden was stigmatized as a hired convert. It is enough, however, to tax his memory with the flattery of a base and bigotted court in the proof of his own degrading dedications, without pronouncing on the inmost secrets of the human heart, and assuming the insincerity of motives which could be known only to himself. It is hardly charitable to suspect motives which malignity itself can only call suspicious. The most important poetry, out of the limits of the drama, which he wrote under King James's auspices, was "The Hind and the Panther." His pen was more unprofitably engaged in a prose apology for the conversion of the Duchess of York to Catholicism; and in translating the life of Francis Xavier, one of the last saints of the Roman calendar. Believing, as he did, in astrology, there was nothing in the wildest of Popish legends which his strong imagination might not be able to digest. The Revolution soon after blasted all his projects; placed the laurel on the head of his enemy Shadwell; and, in spite of the kindness of Dorset, who, when obliged to deprive him of his office, made him munificent presents, obliged him to resume his theatrical labours as an immediate resource. During the reign of King James, he had contributed to a miscellany published by Tomson, some of those translations from Virgil, Lucretius, and Horace, to which Garth has applied the eulogy formerly paid to D'Aubignier, that it was uncertain whether the deed or the living owed him the greater obligation. There is more quaintness than truth in this assertion. The living are positively indebted to him for a fine poem in the English Eneid; but from Virgil's obligation to him, we must deduce all the beauties of the original, which are lost or diminished in their translated form. After the Revolution, he contributed to the materials of two other miscellanies published by Tomson, in concern with his two sons, and other inferior assistants; and being now retired from the stage, bent his thoughts to the great task of translating Virgil. He wrote the first lines of this performance with a diamond on a pane of glass in one of the windows of Chesterton House in Huntingdonshire, the residence of his kinsmen John Dryden; but the antiquary may now search in vain for that frail memorial, for the house of Ches-
tation was, in 1807, pulled down for the sake of its materials. His probable profits from the work have been calculated at £1,300. His last work was the miscellaneous of 1700; which took its name from its most important contents, the Fables. At this period, on the verge of 70 years of age, he had bargained with Tonson to furnish 10,000 verses for 250 guineas; but he received from the Duke of Ormond, for the dedication, £1,500.

Amidst the warfare of criticism, and the toils of literature, his age was now afflicted by the gout and gravel. He had also an erysipelas in his leg, and a neglected inflammation in one of his toes speedily turned to gangrene. He refused to undergo amputation of the limb, telling the surgeon that he cared not to lose it, for the sake of protracting an uncomfortable life to the other members, and closed his existence on the first of May 1700. Dr Garth pronounced a funeral oration in Latin over his grave.

The merits of Dryden are so strong and diversified, that they collectively rank him as one of the greatest of our poets; and yet the destiny of his laborious life prevented him from accomplishing any one production, which can be pronounced at once excellent, extensive, and original. Not one of his dramatic pieces is a master-piece, though many of them bear tokens of the hand of a master. He never reached in the drama to an original conception of character; and he had no talent for pathos, an indispensible qualification in dramatic writing. The design of his allegory the " Hind and Panther," is preposterous. In his Fables from Chaucer and Boccacio, he has only filled up the outline of early masters; his merit in those pieces reaches only to colouring and expression, not to design or invention. In his " Absalom and Achitophel," his plan of scripture parallel was not original; and the story of the poem is necessarily meagre and defective. As an ode writer, however, it would be only repeating proverbial praise to speak of his "Alexander's Feast," and not only from that, but from innumerable instances of his magnificent imagination, not a doubt can remain, that he was equal to the conception, as well as conduct, of extensive and original creations in poetry. The whole history of his life anticipates an answer to the question, why did he not execute such a work? The readiness of his pen was indeed taxed to the utmost; but it is evident, from his constant recourse in narrative to the materials which he could borrow or translate, that he despaired of having leisure to invent. At the same time, his power of managing stories at second hand, his touches of addition and renovation, and the air and spirit with which he personates the character of an original narrator, is so like originality itself, that we forget all his debt of the materials to another, and regard the facts, the contrivance of incident, and whatever had been left to him by a predecessor, as only fortuitous advantages, which none other could have used; or like the strings of some instrument of music, which no other hand could have readjusted and taught to produce the notes of enchantment. This remark on his art of renovating poetical narrative, we conceive to be peculiarly applicable to his imitations of Boccacio and Chaucer. His translation of Virgil cannot be considered, without a comparison with the original, more favourable to the English poet. The circumstance which leaves the deepest impression of his genius, is his portraiture of moral character. As a story, "Absalom and Achitophel" has neither interest nor regularity, but it is a great gallery of historical portraits,—sketched with the very science of moral physiognomy, taken from life, and full of the spirit and air of vitality, and touched with a singular union of gay satire, and of dignified intellectual energy. The polemic may be wrong, but as a polemical poet, Dryden has always the art to make his fancy potently illustrative of his reasoning; and his reasoning has, for all the views of poetry, both a bold and familiar aspect of command. With majestic numbers, he seldom or ever reaches to the sublime; his manner, for ever recurring to carelessness and flatness, has not an ethereal or supported tone of inspiration, but it always assumes an eloquence (keeping apart his bad tragedies,) in which the judgment is mainly, and the imagination profuse, and the force and fidelity of language at once preserved and heightened by the noblest structure of English rhyme. DYPYIS, a genus of plants of the class Hexandria, and order Trigynia. See Botany, p. 167.

DSCHOUFUFTKALE, or Duchufutkal, is a town and fortress in the Crimea, built on the summit of a mount, which rises into a peak on each side. The town contains about 200 houses, and about 1200 inhabitants, who are principally Karaite Jews. The chief part of each house is occupied by the women, but the master has his own private apartment, where he smokes, sleeps, and receives his friends. The principal objects of interest in this place are the remains of a stately mausoleum, erected for the daughter of one of the khans of the Tartars, and the cemetery, or "Field of Dead," belonging to the Karaite Jews. This cemetery, situated at the beginning of a valley, and without the town, is a beautiful grove, filling a chasm of the mountains, and solemnly shaded with lofty trees and impending rocks. There are ranges of tombs in the form of sarcophagi, and the tombs bear Hebrew inscriptions, the most ancient of which is 338 years old. On one of the oldest was the following inscription:

CECY — JOSPEH, FILS DE SCHIBAHTAI
LE TONBEAU — 5204,

a date which corresponds with the year 1445 of our era. As there is no water in the town, the inhabitants are obliged to convey it on the backs of asses from a spring in the defile, and deposit it in a reservoir cut in the rocks.

The inhabitants of this town keep their shops at Batcherseri: they go there on horseback in the morning, and return home in the same manner in the evening.

See Reuilly's Travels in the Crimea in the year 1803, chap. vi.; and Dr Clarke's Travels, vol. i. p. 479. See also Batcherseri. (‡)

DUBLIN, a county of Ireland. It is situated in the province of Leinster, and is bounded on the east by the Irish sea; on the north, by East Meath; on the west, by East Meath and Kildare; and, on the south by Wicklow.

This county is not remarkable for its scenery. In aspect general, it is flat and uninteresting. On the sea-coast, however, where there are many bays and creeks, it affords some picturesque views. And the prospect across the Bay of Dublin, towards the south, is extremely grand and magnificent. Approaching to Wicklow, there
is a continued series of gentlemen's seats, which are laid out and adorned with much taste. On the borders, it has all the rocky and mountainous features of that county. In general, the soil is very cold and unfruitful. In some parts, the subsoil is so calcareous, that it effercesces when exposed to the action of an acid. The climate is warmer than might be expected. In the five years ending 1800, the medium atmospheric heat was 50° 15'; the maximum being 81° 50', and the minimum 14° 50'. The range of the thermometer is about 36°; that of the barometer about 27.5 or 2.4 inches. The average quantity of rain that fell at the botanic garden near the city of Dublin, for the 10 years ending 1811, was 22,988 inches. The south-west wind is the most predominant. The south-east is the most pro-

flice in rain.

Agriculture is not in a remarkably flourishing state. The system pursued is an unskilful one; and of course the quantity of produce is unequal to the advantages enjoyed. The grain, however, is generally good in quality. Very little wheat is raised. barley is seldom sown. Oats and potatoes are standard crops. There is almost no flax cultivated. In 1608, about 45 acres were under hemp.

The following is an average view of the quantities of seed used, and of the produce per English acre. This table is made from the statements of Mr Wakefield; but from the produce assigned to oats and potatoes, we suspect his statements are, not incorrect, so far as they go, but of insufficient extent and variety to afford a fair average.

The breeds of cattle in this county are multifarious. Every different kind almost is to be found here that is to be found in the island. But little attention is paid to the improvement of them. In the city of Dublin and its neighbourhood, there is a vast number of cows kept for the dairy. They are chiefly of the English and Dutch sorts. Their average produce of milk in summer is eight quarts, and in winter five quarts per day. They sell at from 10 to 20 guineas each. In this county the farmers have no flocks of sheep.

The fuel made use of is furze, turf, and coal import-

ed from the west of England. A good many trees are to be seen around gentlemen's seats, but wood is not abundant. The weeping, or Hertfordshire elm, is frequently raised.

The weights and measures of this county are various. In the district of Fingal, 5 stone is equal to a bushel of wheat; 4 stone = do. of barley; 3½ stone = do. of oats; 5 stone = do. of potatoes; 4 stone = do. vetches. In the city of Dublin, 20 stone is equal to a barrel of wheat; 16 stone = do. of barley; 14 stone = do. of oats; 20 stone = do. potatoes; 8 barrels = 1 ton of coals; a kish of turf = ¾ feet by 2, and 3 feet deep; a perch = 21 feet in length, and 8 feet in width; a barrel of roach lime = 40 gallons of 217¾ cubic inches; a stone of rough tallow = 15 lbs. The common lawful

English weights and the Winchester bushel are also in use. Hay, garden, and flax seed, are sown by the bushel.

In some places labour is paid in money, and in other places in money with conveniences, such as a cottage, labour, &c. The following is a list of prices for the year 1811. A man the year round L. 23; 8; a woman do. L. 15; 12; carpenter per day 3s. 10d.; mason do. 3s. 8d.; slater do. 4s. 3½d.; quarryman 2s.; thresher do. 2s.; mason per 21 feet 1s. 1d.; slater per square 2l.; bricklayer per perch 2s. 2d.; cart and horse per day 3s. 4½d.; grazing a cow per week 3s. 9½d.; do a horse do. 7s. 3½d.; fencing per perch, ditch 7 feet by 6, 4s. 4d.; sea coal per barrel 8s. 4½d.; culm per ton 3s. 3½d.; furze per thousand 8l. 10s.; bricks per thousand 2l.; lime per barrel 1s.; plough timber 1l. 2s. 9d.; a car mounted 4l. 1s. 1d.; bran per barrel 6s.; potatoes per stone 6d.; salt butter per cwt. 5l.; fresh do. per lb. 1s. 4d.; hay per ton 4l. 1s.; whisky per gal-

ton 9s.; ale per quart 3d.; porter per gallon 1s. 2d.; beef per lb. 7d.; mutton do. 6d.; veal do. 10d.; pork do. 4d.; lambs per score 10½l.; eggs do. 10½l.; cheese per lb. 1½d.; bacon do. 1st.; shoeing a horse 3s. 6d.; brogues per pair 7s.; shoes do. 9s.; leather per lb. 1s.; salt per stone 1s.; a spade 4½d.; shovel 2s. 6d.; Swedish iron per cwt. 1l. 10s.; wool per stone 1s. 6½d.; fowls per couple 4s.; turkey 2s. 6d.; goose 1s. 7½d.; wheat per barrel 2l.; barley do. 2l.; oats do. 1½s.; malt do. 2s. 5s. 6d.; flour, 1st per cwt. 2l. 12s. 2d. do. 1l. 18s. 3d. do. 1l. 6s.; oatmeal per stone 3s.; harvest of hay or corn per day 2s. 5d.; day labour of children 7d.; mowing grass per acre 8s. 8½d.; rabbits per couple 1s. 10d.; milk per quart 2½d.; Rush ling per cwt. 1l. 1½s.; corn acre of meadow 7l. 10s.; do. of potato land 10l.

Among the largest land proprietors in this county are Mr White, Mr Hamilton, Mr Talbot, Lord Long-

ford, Lord De Vesci, and Lord Mountjoy. None of the estates are very extensive, which circumstance is probably owing to the neighborhood of a great commercial city. The size of farms varies very much. Leases also are of various terms, except that they generally in-

clude a life, in order to command a vote. The land, from its proximity to the capital, is a more marketable commodity here than in most other counties of Ireland. The rental must be high, not however from the quality of the soil, but from the number of acres attached to villas and country seats, and other local advantages. Mr Wakefield makes its average over the whole county to be not less than L.3 per acre. The whole rental at this rate would be about L.426,130 in Irish estimate, both of land and money.

The only river of consequence is the Liffey. It rises in the county of Wicklow, runs west into that of Kil-
dare, then turning north-east intersects the county of &c. Dublin, passes through the city, and a little below falls into the Irish sea. From the Liffey a canal has been made, which joins the Shannon at Clonmel. There are a good many bays and creeks. That of Dublin is very beautiful. The principal harbours are those of Dublin, Rush, Skerries, and Balbriggan.

In this county there is manufactured a strong kind of 7-8th dowlas, and also some 9-8th and 5-8th sheet-tures. Goods of this sort are sold in the Drogheda market, and find their way in an unfinished state into the country markets of England.

On the Liffey there is a considerable salmon fishery, belonging to Sir W. Worthington, extending from Is. fisher's land-bridge to the light-house at Polebeg. It employs
about eighteen or twenty men. From the beginning of January to the end of September, it yields from 90 to 200 fish every week, which sell, on an average, at about 17s. each. This county is distinguished by the goodness of its cels: They are found in great abundance in Tullaghreen river, and in the neighbourhood of Fieldston. The quality of these is excellent. They are called silver cels, on account of a remarkably white and clear colour, which they are supposed to derive from the superior purity of the water, which runs over a bed either of sand or gravel. The mud-cels are yellow bellied, and of a less pleasant flavour. Sand-cels are found in great plenty along the coast, and furnish an agreeable and wholesome supply to the necessities of the poor. The number of herrings for fishing at sea, belonging to the county in 1801, was 87, carrying each seven or eight men, and employed, in the proper season, in catching cod, ling, haddock, ray, herrings, &c. They receive a parliamentary bounty of 20s. per ton; but it is complained, that this bounty is become too small, on account of the increased expense of the coasts used in the occupation. Besides these, there are about twenty smacks and five seine nets occupied in the salmon fishery, between Dublin-bay and Dunleary. At Dunleary there are also eleven yaws, and at Bulloch seven, which fish for whiting, pollock, and herrings. At lusk and Skerries, the art of curing the cod and ling has been carried to very considerable perfection. The cod and ling cured at these places are reckoned preferable to the foreign fish. The sturgeon has sometimes appeared in the bay of Dublin. In September 1746, one was caught between that place and the Isle of Man, which measured six feet long, and three broad in the thickest part. The sprat is found in the Liffey, between Dublin and Island-bridge, and in several other places. Good lobsters are found at Howth and Lambay. Lobsters and crabs are also brought from Galway and Wexford, and fattened in coops at Bulloch. There are two artificial, but not very productive beds of oysters, one opposite to Cold Harbour, and the other near Sutton. They were transplanted from Arklow. The oysters were injured by being taken up too soon, to answer the great demand. Several natural beds are mentioned by Dr Rutty. In one of these, which was situated east-north-east from Ireland's Eye, and lay at the depth of eighteen or twenty fathoms, the oysters were so large as to be of the size of a horse shoe. Porpoises are frequent on the Dublin coast.

The minerals found in this county are marl; sand fit for all uses; limestone; excellent granite, which is so abundant as to have in some measure supplanted the Portland stone; good freestone; lapis Hibernicus, or Irish slate, of which there are large rocks on the coast between Rush and Skerries, that in some places exhibit a vitriolic efflorescence: copper and lead, of both which there were mines formerly wrought at Lough Shinney and Old John Bar; ochres of different colours; potter's clay; beautiful pebbles; porphyry, and crystals. On this part of the subject the reader may consult Stephens' Notes on the Mineralogy of Part of the Vicinity of Dublin. In several places there are mineral waters. Of these, a full and accurate account is given by Dr Rutty in his Natural History of Dublin. The village of Lucan, situated towards the south, and of great beauty, is celebrated for its spa, which resembles that of Aix-la-Chapelle and Bruges, with this exception, that its waters are cold.

Formerly Dublin sent ten representatives to the Irish Parliament. It now sends five members to the Imperial Parliament; two for the county, two for the city, and one for the university. The freeholders of the county are very numerous, and very opulent, and therefore not subject to political influence in the choice of their representatives. It comprises, exclusive of the city and liberties, six baronies, viz. Belruidery, Nethercross, Carlock, and Castleknock, on the north side of the Liffey; and Newcastle and Half Halfathawn on the south. There are 107 parishes, 20 of which are in the city. There are two regiments of militia, one for the city and one for the county. Four grand juries are impannelled every year, in each quarter. Two of these are presenting juries.

Dublin is one of the four ecclesiastical provinces into which Ireland is divided, and comprehends five sees under four prelates. The see of Dublin, of which the first mention we find is in the 7th century, embraces the whole of the county, the most of Wicklow, and part of three others. It was erected into an arch-bishopric in the year 1132. In 1214, the bishopric of Glandalough, founded in the 6th century, was incorporated with that of Dublin, and constituted a church. Patrick, Dublin, consists of the dean, the precentor, chan-}

Ecclesiasticall division.

ceillo, treasurer, the archdeacon of Dublin and Glandalough, and nineteen prebendaries. The members of the collegiate chapter of Christ Church, are the dean, precentor, chancellor, treasurer, archdeacon of Dublin, and three prebendaries. The archbishop's revenue was estimated by Mr Young, in 1779, at L 5,000, and lately by Mr Wakefield at L 12,000. Of those round towers, which are so frequent in Ireland, and which, from their being always near a church, are supposed to have been erected for some religious purpose, there are four in this county. One at Clondalkin, one at Lusk, one at Rathmichael, and one at Swords. There was one in Ship Street, Dublin, which was destroyed about thirty years ago.

The length of this county, from north to south, between Meath and the sea, is 304 English miles; and its breadth, from east to west, about 19. Its area is 355 square miles, or 228,211 acres. It contains 198,000 inhabitants, according to Dr Beaufort's statement in 1792. Of these, 14,600 belong to the city. The other 54,000 inhabit 10,560 houses; thus giving about 5.1 souls and 4.2 acres to each house. There is every reason to believe, however, that the population is greatly increased since Dr Beaufort's estimate was formed. According to the return made in 1791, by the inspec-}

Extents and population.

tor-general of hearth money, there were 25,108 houses; of which 7095 paid for one hearth, 2016 for two, 1293 for three, 1571 for four, 1252 for five, 1950 for six, 2123 for seven, 1930 for eight, 1226 for nine, 834 for ten, 1319 for more than ten and less than 44, 6 for 44 to 114 inclusive; 673 were returned as new, and 1213 exempted on account of pauperism. The proportion of Catholics to Protestants is, in many parishes, ten to one; in some it is above twenty to one; in the parish of Narramore it is forty-two to one; but, on an average, it may be reckoned at six to one. In the county regiment of militia there is scarcely a Catholic officer; but many of the privates are of that persuasion. In one company of 200 men there were only 70 Protestants. In the city regiment there are 470 Catholic privates, but not a Catholic officer, commissioned or non-commissioned. See Beaufort's Memoir of a Map of Ireland; Rutty's Essay towards a Natural History of the County of Dublin; Archer's Survey of the County of Dublin; Dutten's Remarks on Archer's Survey; and Wakefield's Statistical and Political Account of Ireland. (»)
Dublin...

Dublin, the metropolis of that part of the united kingdom called Ireland, is situated in the province of Leinster, nearly in the centre of the eastern coast of the island, on a fine stream, at the west end of a deep bay; and distant eight miles from its opening into the Irish Channel; 60 miles west from Holyhead, in the Island of Anglesea, in Wales; 330 north-west from London. It is situated in North Lat. 53° 2' 2", and West Long.-from Greenwich 6° 15', and is bounded by the county of Dublin.

The bay, at its entrance, is about five miles broad, and gradually opens to the breadth of seven, on the north and south beach. The Hill of Howth, which is a peninsula on the north side of the bay, and the rising grounds of Rochestown on the south, direct the view from the bay to the surrounding country, which gently swells from the north-east to the west for six miles, and to the south-east and south-west rises into lofty mountains, at the distance of twelve miles: the space west of Howth, to the rising ground, is filled by the view of two islands, which have a grand appearance, viz., Ireland's Eye, at the distance of a mile; and Lambay, at the distance of seven miles.

The bay, at the distance of five miles from its entrance, is divided into north and south by a mole and parapet-walls, which extend into the sea 17,734 feet, on the right of the stream of the river, during the ebb. It was begun in 1748, and finished in 1755. This mole, for 7948 feet, is 40 feet wide, and has three wharfs to descend to the strand; and the whole road is five feet above the highest water-mark. The house at this part is called the Block-house; and from this to the Light-house, the road is formed of 9816 feet of large blocks of mountain granite, strongly cemented and cramped with iron: the road is 28 feet wide, sloping to 32 at the bottom; and five feet above the highest water-mark to the Light-house. Vast solid masses of stone were sunk in chests, and afterwards guarded by solid masonry, 85 feet broad at the base; and on this was raised a circular structure of white hewn granite, three stories high, surrounded by an octagon lantern of eight windows, tapering to the top. Each story is strengthened by arch-work: a stone staircase winds round the building to the second story, where an iron gallery surrounds the whole. The lantern is supplied with large oil lamps, and reflecting mirrors. This building, and the wall, afford a certain direction for the navigation of the bay, to the mouth of the river. A line drawn from this, due south, forms the eastern boundary of the city jurisdiction.

The city is divided into north and south by the river Anna Liffey (Swift River), over which there are six bridges: four are built of hewn mountain granite, and part of the piers; the cornice and balustrade are of Portland stone. They are 60 feet wide between the balustrades, and have a raised foot-way on each side, and double rows of globes. The river, in its embankment, is 150 feet wide to the east of Carlisle bridge, and rises thirteen feet at high water: it is 120 feet wide at the western bridge, and rises seven feet. The improvement of the city by quays has been the work of the last century; and at present they are rebuilding, of mountain granite, with walks at the parapets.

The buildings of the city now occupy 1600 acres: from east to west it is two miles and a half long; for a mile from the west it is nearly square; and for the other mile and a half it is from north to south one mile and three quarters. Dublin contains 671 streets, all laid out since 1720. The streets are from 40 to 50 feet wide; those built since 1774, are from 50 to 60 feet wide; and all of them have flagged foot-ways suited to their breadth. In 1610, the walls of the city were built: the circuit did not exceed a mile; and the castle occupied the southern extremity. The city, and adjoining ground, is now surrounded by a road, 60 feet wide, with footways communicating with all the avenues, and distant nearly two miles from the castle: it is kept in excellent repair by a toll. The elevation of that part of the road, which is on the north-west and north-east, affords some most beautiful landscapes. Part of his Majesty's park, the Phoenix, is within this circuit; it is so called, from a Corinthian fluted pillar, 30 feet high, surmounted with a phoenix, erected by the Earl of Chesterfield, the viceroy in 1747. This has been always open for the citizens. There are, in this park, above 700 acres; and in different directions there are enclosures and mansions for the viceroy, the secretaries, rangers, and some grantees. There are also a fine military hospital; a large military school for the children of soldiers, with a beautiful church for them; a salute-battery of twenty-one guns, and a magazine. None of these buildings interfere with the views, or with each other. The park has two fine sheets of water, is well stocked with deer, diversified with copses, woodland, and open grounds, and is without hedges or trenches. It has the view of the river for two miles; above which, at the distance of 30 perches, it rises abruptly about 50 feet; and thus commands a full prospect of the city, the bay, and all the surrounding country. The park is connected with the south side of the river by a bridge on the circular road, of singular beauty: the arch is elliptical, and 104 feet in diameter; and the key-stone is 22 feet above the high water mark. It is 326 feet in length, 38 in breadth, with flagged footways: The base is of white hewn mountain granite; and the piers, cornice, and balustrade, of Portland stone, with two rows of lamps. It is called Sarah-Bridge, out of respect to the memory of the Countess of Westmoreland, who laid the first stone of it in June 1791.

The ground from the river, and four small streams of distant courses which fall into it, rises near them from 24 to 40 feet; so that the buildings of the city are very healthful, and nearly all command a prospect of the surrounding country.

The embankment of the river, from the strand, for 240 perches, between the city and the harbour, on the north side, and on the cast for 360 perches, to the Bay, with solid walls and sluices, was made at the expense of the Corporation. The inclosure was divided into lots, and let to fee-farm, with the burthen of repair and maintenance, under the view and control of the city magistrates, and lately of commissioners, incorporated in 1756. The same was also done on the south side by Sir John Rogerson, by a solid wall and sluice draw-d to the Liffey; and on the east side by a wall and mole of 380 perches to the left of the Dodder, a mountain-river which runs at this point into the Liffey. Over the Dodder there is a commodious bridge, which leads to the south wall. All this embankment is under the care of commissioners.

The houses are built of good brick, and the fronts Buildings are commonly of that finer sort called stock-brick: they are generally five stories high, of which the cellars are one. In the streets laid out by the commissioners incorporated in 1758 and 1774, the houses are generally six stories, and so well built, that they are valued and sold as bearing equal interest for sixty-one years.
In the year 1791, the city contained 22,000 houses, and the inhabitants were estimated at 226,000. Since that period, more than 4000 houses have been built, which, at the same calculation, would amount to 278,000.\* The supply of corn, flesh, fowl, and fish, is very abundant. The fuel is supplied from Scotland and Cumberland, and from the bogs through which the two canals, the Grand and the Royal Canal, run. There is great plenty of turf.

The city is supplied with water on the north side by the Royal Canal, which communicates with a basin handsomely laid out, and provided with branches for its distribution; and, on the south side, the sheet of water is enclosed by a mole and a terrace-walk, neatly planted with a thickset hedge and elms. This reservoir is filled constantly by a stream from the mountains, and from the Grand Canal; the water of the two reservoirs is distributed through the city by double ranges of pipes; a great part of which are new, and all hereafter are to be of metal. Every house pays the water-duty, and is therefore supposed to have a branch from the adjoining main.

The care of the food, fuel, watching, cleansing, lighting, requiring the pavement, the roads, the parapets of the quays, the sewers, the jails, of decayed houses, and of the removal of all nuisances, is divided among the citizens and inhabitants by special acts of Parliament; and these incorporations are empowered to discharge the trust in a very effectual manner, by fine, distress, and imprisonment.

The barracks, situated on an elevated ground at the north-west side of the river, about 30 perches from it, and rising above the adjoining streets 30 feet, were opened in 1794, and are fit to lodge 4000 infantry and 1000 cavalry. They have four large squares, three of which are for the infantry, and one for cavalry; the three to the south occupy a front of sixty perches, and that to the east twelve. Since 1795, barracks have been erected in different parts of the inclosure within the circular road, which can accommodate 10,000 men.

On the opposite side of the river stands Kilmainham Hospital, on a site of 64 acres, a part of the royal park, erected in 1683, at an expense to the army of nearly £4,000. There belong to this establishment resident and out-pensioners; it is quadrangular, with a spacious area in the centre. The chapel and dining-hall occupy the north side; the portraits of the sovereigns decorate the dining-hall, and the centre of this hall is ornamented with a spire and clock. The whole building is four stories high, with an open piazza on the ground and corresponding corridors over the piazza, which renders the communication through the centre very agreeable. The invalids do duty. There is a military road from it to the barrack bridge, to give the commander in chief, whose stately residence is within this part of the park, a speedy communication with the barracks.

The Castle, the town residence of the viceroy, occupies two squares, all rebuilt in the last century, except the south-east tower, called the wardrobe tower: The south-west tower is called Birmingham tower. The entrance is on the north side from Castle Street, by a stately gate, 80 feet high, surmounted with a statue of Justice, which has a correspondent gate-ornament on the same flank, surmounted by a statue of Fortitude, and both connected by a handsome edifice, called Bedford Tower. The front to the court is decorated with an arcade of three arches, over which there is an octagon steeple, with a cupola and clock; the remainder of the building to Castle Street from the Castle gate, is the guard-house, and the whole is enclosed there by a range of iron palisades.

The guard consists of a captain's company of foot, a subaltern's guard of horse, detachments of artillery and of battle-axe guards. These are dresse" in the ancient habit, and do duty near the presence chamber. They are commanded by a captain, who ranks as colonel, and by two subalterns, who rank as captains.

The centre of the ground plan of the lower court is sixteen feet below the upper, being in the course of a mountain river, which formed the foss of the first projection of the castle. In it are the treasury and other state offices, the armoury, and arsenal. The beautiful Gothic building, the chapel, now nearly finished, fills the southern range. The street leading from the city into the court nearly at its centre, and to the western postern, is parallel and close to the south side of the buildings of the two squares, and is closely bounded on the south by the castle garden, to which a passage is opened by a beautiful range of granite stairs, supported by an arch over the street. This part of the buildings of the upper court is called the garden front, erected in 1740. It is finished with white granite, and ornamented with semicolumns of the Ionic order, and the windows are embellished with cornices and architraves.

The approach to the state apartments is in the upper court, by an open vestibule, projecting twelve feet, and sixty feet wide, and forty deep, supported by Doric columns, leading to a staircase twenty feet wide, with two ranges from the first landing. The presence chamber is over this hall; it is a very fine room in all its proportions.

The hall room is appropriated to the festivals and meetings of the knights of the illustrious order of St Patrick, instituted 17th March 1783. His Majesty is the Sovereign, the Lord Lieutenant, for the time being, the Grand Master, and the Knights Companions are 15. They wear a sky-blue watered ribband, with a metal appendant, of two inches diameter, encircled with brilliants. In its centre there is a saluter of an inch diameter: the interstices of the salter are occupied with the motto, "Quis Separabit," in allusion to the decoration of the centre of the salter, which is the shamrock bearing three crowns. The hall was ornamented with historical and allegorical paintings, by the celebrated Mr Waldrie, during the administration of the late Marquis of Buckingham.

In March 1766, the first stone of the courts of justice, on the north side of the river, was laid by his Grace the Duke of Rutland, in the presence of the Judges, on the site of the Dominican convent, which, at the suppression of the monasteries in 1541, had been retained by the crown for a public office, and used to this period as the Rolls Office. The new buildings were finished, and the courts opened there, in November 1796. The whole range extends 436 feet in length, and 50 in depth. The court yards of the offices on each side, are open to the quay, and separated from it by iron palisades and beautiful gateways of hewn

\* According to the estimate of the late Dr Whitelaw, the population in 1798 was only 172,094; but this is admitted to be far below the real population.
DUBLIN.

mountain granite, with side doors. These courts extend 99 feet to the quay, and are 50 deep; between them the front of the hall projects. It is composed of six columns of the Corinthian order: in the centre of these is the principal entrance, with an extensive vestibule. The hall, from which the courts radiate, is circular, and is 64 feet in diameter. The entrance to them from the hall is ornamented with Corinthian pillars and semicolumns; and the stately cupola, of the same diameter, gives bright light to the whole hall, by windows in the sidewalls. Each court has all its suited apartments within itself; and these buildings occupy 235 feet in front, and 50 in depth.

The cupola is ornamented with the busts of the most celebrated legislators, ancient and modern; and the whole building is insulated.

The removal of the courts from the centre of the city, where they were held for a century, caused a great depression in the value of the buildings. To remedy this, there is a Parliamentary grant, in 1807, for the improvement of the city on the south side of the river to the west of the castle. This expenditure, by widening the streets in this part of the city, with the elevation of the ground, will render it most convenient and wholesome.

The Danes settled on the coast were in possession of the lands about Dublin, and of Dublin, during the greater part of the 10th, 11th, and 12th centuries, and kept it, notwithstanding the victory at Clontarf in 1014, till it was taken by Raymond le Gros in 1171. He was the auxiliary of Dermot MacMurrough, Prince of Leinster. It was erected into a bishoprick in 1038, and to an archbishopric in 1132. St Lawrence O'Toole changed the chapter of Christ Church into a priory. Archbishop Comyn, in 1190, erected St Patrick's Church on the site of an old parochial church, and his successor, Henry de Lomard, erected it into a cathedral. During his administration, the diocese of Glendolough was united to it in 1214, by Cardinal Papire, the legate. The present building of St Patrick's was erected in 1535 by Archbishop Moises, and the steeple in seven years after. The present spire was built by Dr Sterne, late Bishop of Clogher, and formerly Dean of St Patrick's. The chapter, nave, and aisles are in very good preservation. The stalls in the choir are adorned with the banners of the arms, the swords, and the helmets of the Knights of St Patrick; and those of the deceased kings are in the Chapter House. The archbishop is the chancellor of the order, and the dean is the register. The monuments in the aisles, and on the left of the altar in the chancel, are very beautiful.

The chapter consists of six dignitaries, twenty prebendaries, four minor canons, and fourteen vicars choral. There is a library belonging to this cathedral, of which we shall afterwards give an account.

Christ Church, the ancient cathedral of Dublin, lost its rank by its change into a priory; and on the dissolution of the monasteries in 1541, it was formed into a collegiate church, with a dean and chapter. At present the Bishop of Kildare, for the time being, is the dean, and there are besides four dignitaries, three prebendaries, six vicars choral, and seven stipendiary chaplains. The ancient building, erected by Archbishop Comyn, in 1190, was burnt in 1293. The present building is kept in good preservation, and the monuments are interesting. The Archdeacon of Dublin has a stall in the choir, and a voice and seat in the chapter. There are besides of the established Church, nineteen churches and twelve chapels; of the Roman Catholic communion, twenty-six chapels; two meeting houses of the Church of Scotland, seven of other Dissenters, four of Methodists, two of Quakers, one Luthern Danish, and one French Calvinist. St Catherine's, St George's, and St Werburgh's, are finished in a fine style; St Thomas's and St Anne's are also well built; but the fronts are left unfinished. St Andrew's is rebuilt in its rotunda form, and decorated in the best manner. All those buildings which do not belong to the established Church have been erected by subscription, and on this account are not of that solid nature which bids defiance to time, or of that external beauty which will attract the attention of a visitor.

There are fifteen parish schools annexed to the established Church, in which 397 children are fully maintained and educated, and afterwards apprenticed. There are also three female orphan houses, under the direction of the established Church.

Every house of worship has also some children under its protection, besides the general and numerous associations for the protection of foundlings and orphans, by private subscriptions, and annual charity sermons. The following institutions, which are incorporated by acts of Parliament, and receive annual grants, are worthy of notice: The Hibernian Society, for the orphans and children of soldiers; the Hibernian Marine Society, for the orphans and children of decayed seamen, in his Majesty's navy; the Blue Coat Hospital, for the children of reduced freemen of Dublin; the Foundling Hospital; the House of Industry; the Incorporated Society for promoting English Protestant schools in Ireland; the Board of Education; and the Association for discomfitting Vice: besides, the Hibernian Bible Society, not yet incorporated.

The hospitals for the reception of sick and wounded, or maimed, are eight; one for lying-in women; one for the blind and gouty; two for lunatics; one for incurables; one for teaching the blind; three for fever; three for female penitents; one for a particular infectious distemper; one to re-establish health after cure, and procure character; one for the cow-pock institution; one cow-pock dispensary for ditto; and five general dispensaries of medicine.

The Societies for relief from poverty, &c. are the Sick and Room Keepers Society; two houses of refuge; the Strangers Friend Society; the Literary Teachers Society; the Incorporated Irish Musical Fund Society; the Charitable Loan Society, for lending out money interest-free to tradesmen; Meath Charitable Loan Society; the Dublin weekly and daily schools; the Sunday and daily schools; the schools of the House of Industry. It is generally estimated that education is given to 9000 poor children.

The university of Dublin was founded by Queen Elizabeth, in 1591; its charter was renewed, and statutes compiled by Archbishop Laud, in 1637. The monastery of All Hallows was dissolved in 1541, and granted to the citizens of Dublin, who regranted it in 1590, for the site of the university. No part of the ancient buildings remains. The present building consists of two squares: the first is modern, and executed from the designs of Sir William Chambers; the front, which looks to the west, is built of Portland stone, and is highly decorated with Corinthian pillars and other ornaments; it is upwards of 340 feet in length; over the vestibule, which is an octagon terminated with groined arches in the centre of this front, is the museum, a fine room sixty by forty feet, furnished with a great variety of curious natural and artificial productions. The area of this
square is 316 by 212 feet, and entirely built of Portland stone, by grants from Parliament to the amount of L. 40,000. It contains on the north side the chapel and dining hall, and on the south the theatre: the front of this is decorated with four Corinthian pillars supporting a pediment; its interior is 98 feet long, including a semicircular recess of 30 feet diameter, 40 broad, and 44 feet high. A rustic basement supports a range of pillars of a composite order, highly decorated, from which the Mosaic ceiling rises in groined arches; and the following pictures are hung between the pilasters: Queen Elizabeth, Primate Usher, Archbishop King, Bishop Berkeley, William Molyneux, Esq. Dr Baldwin, Lord Clare, and the Right Honourable John Foster, Esq. The monument of Dr Baldwin, a former provost, is in this theatre; it is the work of Mr. Hewson, who executed it at Rome: a large sarcophagus of black marble supports a white marble mattress, on which the provost is represented in a recumbent posture, larger than life, with a scroll representing his will, (amounting to L. 80,000, bequeathed to the university,) in his left hand, on the elbow of which he supports himself, and holding his right hand extended open; a female figure, in deep grief, representing the university, leans over him, and he looks up to her with resigned complacency; at his feet there is an angel holding a wreath of palm in his left hand, who points up to heaven as his reward; behind these figures there is a magnificent pyramid of variegated Egyptian porphyry. This successful proof of the taste and ability of their countryman for this important work, does immortal honour to the artist, and to the persons by whom he was selected. He received L. 2000 for it.

The chapel on the north side, and opposite to the theatre, is executed in the same style of architecture. These two buildings advance about twenty-five feet into the square, and form the boundary of the building, erected at the expense of parliament. The dining hall is a detached building on the same side, of Portland stone, with a stately ascent by a range of stairs the whole extent of the portals, 35 feet high, 35 feet wide, and 70 long, with an anti-room 35 feet broad by 30 deep, capable of entertaining 400 persons; and over it is the Historical Society Chamber, of the same dimensions, where students of a certain standing meet to exercise themselves in oratory upon chosen subjects, for excellence in which gold medals are given. The eastern side of this square is of brick, and likewise the entire building of the inner square, excepting the library, which occupies the south side of it. It is built on a piazza, and is of hewn stone, with a magnificent Corinthian entablature, surmounted by a balustrade. The great repository room is 210 feet long, 40 feet high, and 40 broad. The bookcases are in recesses which advance from each window, and are formed by the gallery over them, the balustrade of which is ornamented by the heads of illustrious personages, sculptured in white marble by eminent artists: the remainder of the extent of the building is occupied by the grand staircase and reading rooms. Several rooms parallel with the piazza are occupied by the various apparatus of instruments, for conducting experiments in natural philosophy. These apartments look into the Fellows' garden. The library consists of 40,000 volumes, collected by Archbishop Usher, Dr Gilbert, Dr Palliser, Archbishop of Cashel, and by several persons who gave small parcels, valuable either for the rarity or exactness of the editions; and besides these, the college bought the books of the Bagel library, which was valued at L. 20,000, though they were sold at a rate much less. There are also in the library several hundred rare and valuable manuscripts, relating to the Irish language and history, the Scriptures, arts, and sciences. The college park, to the east of the inner square, contains about eight acres, and is intersected by spacious gravel walks, which have the advantage of sun and shade, from the well-arranged distribution of the plantation. The printing-house, with a stately front of white hewn granite, is on the north end of the great gravel walk, and opposite to it is the anatomy-house. Among many other rarities in this house, is the celebrated wax work of M. de Houe, of Paris, a work of forty years labour, representing the whole progress of the human fetus, in figures as large as life; and the valuable gift of the first Marquis of Lansdown. These figures are in a separate room, in large glass cases, and are in fine preservation. For an account of the Observatory, see OBSERVATORY.

The provost's house is on the south side of the western front of the college, and to the west of the Fellows' garden: it is built on the plan of Burlington-house, noticed in Campbell's Vitruvius Britannicus. The whole site of the college ground occupies twenty-five acres. Its government is in the provost and seven senior fellows, with appeal to the chancellor, vice-chancellor, and visitors. There are besides fifteen junior fellows, who are the teachers; five royal professors, of divinity, common law, civil law, medicine, and Greek; also Archbishop King's lecturers, of divinity and of Greek; two royal professors of modern languages; Erasmus Smith's professors, of mathematics, Oriental languages, oratory, natural philosophy; Andrews' professor of astronomy; Mrs Donnellan's lecturer; the professors of anatomy and surgery, of chemistry and of botany; Sir Patrick Dunn's professors, of the institutes of medicine, of the practice of medicine, and of the materia medica, and pharmacy. The students are ranked in three classes,—fellow-commoners, pensioners, and sizars. The expense of the first class is about L. 100 per annum, and the second about L. 70; the third class, about thirty in number, are chosen after examination as the best answerers, and admitted into the establishment to have commons as a premium.

The revenue of the college arises from the estates in the northern counties: the distribution of it belongs to the board of senior fellows, each of whom has L. 1000 per annum, and the second about L. 70; the third class, about thirty in number, are chosen after examination as the best answerers, and admitted into the establishment to have commons as a premium.

Dublin. 

The College of Surgeons is a stately building of mountain granite, on the west side of Stephen’s Green, and is provided with all the apartments suited to the profession, with a spacious theatre for anatomy, a burial-ground, a museum, and a library. The secretary is resident, and has apartments with every accommodation.

The Duke of Leinster’s town residence, and that of the Marquis of Waterford, have spacious enclosures, and are built of Portland stone. Those of the Earls of Charlemont, Powerscourt, and Aldborough, are also built in the same manner, but are not enclosed in the front. The Earl of Moira’s house was built in the last century, and though of brick, is very magnificent. The houses of the other noblemen are built of brick, in the modern fashion, and in appearance are not to be distinguished from the other buildings, but by the range.

The public buildings connected with trade, are the Bank, the Custom-house, the Royal Exchange, the Commercial Buildings, Linen-hall, the several halls belonging to the guilds of the trades carried on in the city, and the Post-office.

The Bank is on the north side of that large open space before the west front of the college. It was the Parliament House, and was begun in 1729, during the administration of Lord Carteret, and finished in 1799, at the expense of L.40,000. The lantern and western fronts, with the circular curtains connecting them with the south front, cost nearly as much; and the court of proprietors has added greatly to the internal convenience, in addition to the expense of the building erected for the accommodation of the guard: it is built of Portland stone. The grand portico in College Green extends 147 feet: it is in the Ionic order. The centre vestibule is in recess 40 feet, and the entablature of the advancing vestibules of the portico is ornamented with statues. The cash office is the hall which leads to the rotunda, in which form the House of Commons was built. This room, by the throwing down of the House of Commons, is illuminated from the north side, near the ceiling, which is 50 feet high, and by the reflection of a row of mirror windows on the opposite side. The room is 75 feet long, 53 feet wide, and 50 feet high. The offices are numerous and convenient; and every precaution is taken for the protection of the whole from injury. The late House of Lords remains unaltered; it is for the court of proprietors; it is 75 feet long, and 30 feet broad.

This company was incorporated in 1789. Its capital was then L.400,000 in debentures, and L.200,000 in cash. The capital is now three millions, of which two millions three hundred thousand pounds are in debentures, and L.700,000 in cash. Its profits are the interest of the debentures, traffic in bullion, and discounts, besides the remuneration for managing the fund. The profits are so great, that the bank stock is at L.302 per cent. which is L.10, 2s. per cent. for the original subscription.

The direction is vested in a governor, deputy-governor, and fifteen directors; under the restriction that five new directors at least are to be chosen every year.

The custom-house is on the north side of the river, to the east of Carlisle bridge, and where the course of the river is the wildest, and confined by the straight embankments to the harbour. The building was begun in 1767, and finished in 1791. It is 975 feet in front, and 300 feet in depth, and has four fronts of different designs. It is composed of pavilions at each end, which unite with the centre by arches. The order is Doric, and is finished with a bold, projecting medallion cornice. In the centre, a portico supports a pediment, which is enriched with a group of figures in alto relievo. They are Hibernia and Britannia embracing. They bear the emblems of Peace and Liberty, are seated in a
naval car drawn by sea-horses, are accompanied by Tritons, and followed by merchants' ships, laden with the produce of different nations, and wafted by the winds. Four allegorical statues, Industry, Commerce, Wealth, and Navigation, are placed on the attic over the pediment. A magnificent dome rises 75 feet above the building, and on it is placed a female statue of Commerce. The pavilions at both ends are decorated with the arms of Ireland in an elliptic shield, supported by the lion and unicorn, and decorated with festoons of fruits and flowers.

The entrances are ornamented with allegorical colossal heads. Over the four columns of the north front are four statues, representing the four quarters of the world. The whole south front is of Portland stone, and the others of white mountain stone. The columns, cornices, and architraves, are of Portland stone. The great room for business is 70 feet long, 63 broad, and 30 high. Rows of columns on each side form open recesses for the offices.

Opposite to the east front there is a large wet dock, which contains 40 sail, and contributes much to the dispatch of business. The total expense of this building is reputed to be L.255,000. The authority of the commissioners extends to the whole kingdom.

The Royal Exchange was begun in 1769, by a parliamentary grant of L.13,500, which purchased the site on the activity leading to the castle. It was finished in ten years, and opened in the beginning of 1779. It cost L.60,000, and was raised by lotteries to which the state lottery. The building is nearly square, and crowned in the centre with a fine dome, supported on the inside by 12 composite fluted pillars, which form a circular walk. Above these pillars are 12 circular windows. The centre of the dome has also a large window that illuminates the whole.

A bronze statue of his Majesty George III. in a Roman military habit, executed by Van Nost, at the charge of the late Duke of Northumberland, is placed on an elevated white marble pedestal, on a range with the columns in the rear, and opposite to the great entrance. The geometrical oval staircases at each end of the north entrance lead to the coffee-room and the other apartments, which are all occupied for business relating to merchants. The building on three sides is of Portland stone, in the Corinthian order, with their suited entablatures. The north front has a pediment, with a projection of ten feet; and the west front has only a projection of the entablature supporting a balustrade which surrounds the whole building, excepting the interruption of the pediment of the north front. The straight opening of two streets to the north front, gives a full view of its elevation. At the distance of 120 perches, the acclivity of the ground rendered it necessary to protect the ascent by a balustrade and walk. The balustrade is supported by rustic work. The trustees are the lord mayor, sheriffs, city representatives, treasurer, senior master of the guild of merchants, and twelve merchants. In a niche in the western staircase, there is a beautiful pedestrian statue of Dr. Lucas in white marble, in the attitude of addressing an assembly, and placed on a pedestal. There is in bas relief on the pedestal, a representation of Liberty seated, and ornamented with her rod and cap.

Thirty steps of ascent, by the geometrical staircases to the apartments of the Royal Exchange, were found so inconvenient, that the merchants determined to have on the ground plan a set of offices in a court, where business could be transacted within a minute's walk, which was accomplished by the royal charter Jan. 1, 1798. This company elects 15 members, who conduct the business for one year. Thus in the centre of Dame Street, this commodious building was erected; where a mercantile stranger can have every accommodation he can desire. The debentures of the subscription fund are much above par.

The linen hall is a very commodious building, and was opened in 1728; and from time to time has since yard half received many large additions, which give security and convenience to all the manufacturers and wholesale merchants throughout the year, without expense for the lodging and the showing of their goods. The rooms for this purpose are 400, neatly fitted out. The appointment of trustees by the act of 1709, and the execution of the act by the election of the trustees of the linen and hempen manufactures, raised this branch to the rank it now holds. The exports of linen in 1700, amounted in value only to L.14,112, and the number of yards exported, were:

The corporation halls are all commodious buildings. The weaving hall is decorated with a pediment, supported by a projection, and a fine pedestrian statue of his Majesty George II. in his robes.

The post-office is opposite to the bank, in a commodious range of brick buildings. Finding that the dispatch of the mails is interrupted by the want of a courtyard, a range of ground in Sackville Street, on the north side of the river, and nearly as convenient in point of distance as the present site, has of late been chosen by the government for this purpose. Each mail coach, with its entire company, is to proceed into the court, to which no stranger on foot is to be admitted; then to receive the mail, and proceed in its course through the gate on the opposite side. All the great roads are in right lines from the place chosen. The present establishment has given great satisfaction, by the expedition and punctuality of the delivery, both in the penny post, and country carriage.

The Grand Canal Company was first formed in 1765, and incorporated in 1772. After various difficulties, the sum of L.100,000 was raised by subscription, the object was to open a communication between the city and the river Shannon. In 1768, it was opened for passage boats, from the west end of the city to Sallins, 13 miles; in 1786, to Monasterereven, 224 miles; in 1806, to Shannon harbour, 63 Irish miles from Dublin. Passage-boats by day and night proceed through the whole course of the direct line to Shannon harbour, and to the off-line of the Barrow navigation. They are all well appointed, and accommodated with every necessary refreshment. It crosses the Liffey on an aqueduct bridge of seven arches, and pierces the hill of Downing several hundred yards; runs through a part of the bog of Allen, and falls into the Barrow at Monasterereven. It is navigated by boats of 30 and 40 tons burthen. The supply of the stream is principally from the Great Morrell, twelve miles from Dublin, at the fifteenth lock. The locks are 26 in number, six double and 20 single; the falls in which vary from 4 feet 3 inches to 19 feet 7 inches. The summit level is 202 feet 4 inches above the city harbour in James's Street, 82 feet 9 inches above the Barrow at Monasterereven, and 260 above high water mark in the Liffey in Dublin. The 39 feet 8 inches full deterred the company from engaging in the
Dublin. 175

Dublin has for nearly a century been the staple of all the imports, and the exports consumed in the twelve counties west of Dublin and Wicklow. The communication by the canals has assisted this commission trade. The exports from Dublin are chiefly corn, live cattle, butter, and linen.

The woollen manufacture flourished in the southwest district of the city, when it was stopped by the law enacting a high duty, and thus prohibiting the exportation, about the year 1698. At present the number employed would not furnish an eighth of the consumption of the kingdom; without capital, without machinery, without fuel in any proportion in these several respects to the manufacturers of the same class in England, an observer is astonished at the artifices practised to avoid the small protecting duty laid on by the act of union, the policy of which was evidently to give an opening to human ingenuity in this branch, without a possible prejudice to the interest of the sister kingdom.

The cotton and silk manufactures have their special excellence alone to recommend them. The protecting duty on the cotton goods will shortly expire.

Among the number of hospitals, there is one for lying-in women, which is principally supported by the profits arising from musical entertainments, balls, and card parties, which are given by subscription at the Rotunda, and great assembly rooms in Cavendish Row adjoining the Rotunda. Dr. Bartholomew Moss, a licentiate of midwifery, in 1745, began this charitable institution in South Great George's Street; and finding it not sufficient for this purpose, took a field in Great Britain Street, then at the extremity of the City Buildings, (and now nearly in the centre of them;) and in 1751 expended not only his entire fortune, about L.2000, but also all the charitable donations he had received, and money borrowed to the amount of L.6000. In 1754, the zeal of the Doctor, unable to fulfil his design by the means which he supposed to be within his power, applied by petition to the House of Commons, and obtained not only the L.6000 borrowed, but also the L.2000 of his own property, and L.6000 in addition, to complete the whole design. Its use may be estimated by the following bare account from the day it was opened. From December 8, 1757, to October 31, 1809, there were 64,010 women delivered of 30,831 boys, and 31,129 girls. The usual admittance every year is 2600. The building is incomparably well fitted for its purposes. It is entirely built of brown stone, and ornamented on the north and south with regular architectural fronts. A beautiful steeple is in the front, and semicircular colonnades form the wings. To the east of the house is the rotunda, 80 feet in diameter, with convenient recesses; it is connected with the apartments in Cavendish Row, the front of which is of white granite, and of the Doric order, in the frieze of which the arms of Ireland, the stars of the order of St. Patrick, and the crest of the Duke of Rutland, are agreeably united. These apartments consist of a ballroom 60 feet by 40; a card-room 60 feet by 35; a tea-room 54 feet by 24; a great supper-room 86 feet by 40; a lesser supper-room 54 feet by 24; four dressing-rooms, each 19 feet by 13; a hall 40 feet by 30; a waiting-room 36 feet by 20; a chairman's hall 40 feet by 20; a vestibule 20 feet by 14; and kitchens with all their offices. The physicians are a master, and two
Dublin.

Squares.

The six squares within the buildings of the city, which are all ornamented with great care, and decked with those shrubs which can endure the situation, are never-failing sources of amusement to the numerous well-dressed and orderly assemblies on these promenades. Stephen's Green, the largest of them, being 400 yards by 300, is now given up by the corporation of the city, to be laid out in such a manner as will correspond to the stately memorial of national respect to the Duke of Wellington. A tribute of this nature was, in the beginning of the last century, erected to William the IIId. In 1765 the pedestal was repaired, and the statue replaced.

The equestrian bronze statues of his Majesty George I. in the garden of the city mansion-house, and that of his Majesty George II. in Stephen's Green, are lasting memorials of the talents of Mr Van Nest.

The citizens of Dublin have shown their respect for the memory of Lord Nelson, and of the brave men who fought under his command, by the erection of a turret, ornamented on the outside as a pillar. It is erected in Sackville street, which is 100 perches long, and six wide, and in that part of it where it is crossed by two streets at right angles meeting each other, and of the same extent, having on the south Carlisle Bridge, and on the north the side termination of the Rotunda Buildings. The base is twenty-five feet high, and the dates and places of the four great victories are carved on the monumental slabs. On the west side is inscribed, “St Vincent, 14th February 1797;” on the north, “The Nile, 1st August 1797;” on the east, “Copenhagen, 2d April 1801;” and on the south, “Trafalgar, 21st October 1805.” The base is enclosed by an oval iron palisade, ornamented with tridents and lamps. The ascent to the summit of the turret is by 166 steps: there is there a gallery with an iron quadrangular balustrade, and in the centre a pedestal twelve feet high. On this the colossal statue of Lord Nelson, also twelve feet high, leaning on the capstan of a vessel, is placed.

This city, according to Ptolemy, in the year of our Lord 140, was called Archalea, and Ebiana Civilia. Alpinus, a poet, in mention of it, in 155, changed it into Athlone, in sorrow for the loss of his daughter, who was drowned in the river. In 181, the Irish called it by its appearance, Drom chail coill, the brow of the hazel wood; also Ath Cleath, the ford of hurdles; also Ballin leath, the town at the harbour of hurdles; and Dub leane, the black harbour, and hence is the contraction of Dublin.

The rising of the tide renders the approach to the river, even at low water, so difficult, by the quantity of mud deposited, that it became necessary to lay hurdles on the strand. In the summer season, at low water, the river has not a foot of water in the centre of the city, so that the building of a bridge was no object to the inhabitants. So late as 1610, there were but 50 perches of embankment on the north side about Dublin Bridge, now called the Old Bridge, and at that time the only bridge connected with the city.

The Danes were in possession of the city in the 9th century, in 851, and built the ancient walls to protect themselves from the surrounding inhabitants. Notwithstanding the victory gained by the Irish over them in 1014, near Clontarf, their chiefs kept possession of it, built churches, and founded abbeys, in and near Dublin, 24 years after this period. They remained in possession for 134 years, until they were expelled by the united forces of Dermot Fitzmaurice, or MacMurrough, chieftain of Leinster, and of the English adventurers under the command of Raymond le Gros. The marriage of Earl Strongbow with the daughter and heiress of the chieftain of Leinster, gave the Earl the right to transfer it to Henry II. He granted to the inhabitants a charter, and also encouraged, by the value of the grant, several Bristol men to bring their families and settle in it.

Four years after, he created his son John, then but twelve years old, Lord of Ireland, a title which the king assumed, in consequence of a treaty with the Irish chieftains, who had been harassed by constant wars, which the limited powers of the first chieftain could not check. Thirty-three years after, in 1210, King John met twenty other chieftains, who bound themselves, by treaty, to adopt the English law and customs. In 1216, Henry III. granted a new charter; and the year following he granted the city in fee-farm, at 200 marks per annum. The tolls were collected; two-pence only was paid for a barrel of wine, which cannot now be brought in for less than L. 10 sterling. In 1298, the magistrature was styled provost, and his immediate assistants bailiffs. In 1409, the title of provost was changed to that of mayor; and, in 1517, the bailiffs became by title sheriffs. In 1560, the mayor was decorated by the gift of a golden collar, and honoured with a company of foot guards. In 1665, the additional titles of right honourable, and lord, were added by the king. In 1672, new rules were instituted for the better government of the city, by Arthur Earl of Essex; and these were improved by the act of 1793, the 33d of his present Majesty.

The lord mayor, and twenty-five aldermen, form a board in a separate chamber; and the sheriffs and sheriffs peers, with 96 freemen, chosen by the 25 corporations in their respective halls, in a separate chamber, are the electors of the city magistrates. Sheriffs peers are those who had served that office, or been elected, were excused, and paid the charitable fine substituted for service. When they exceed 48 in number, the juniors have no privilege. The freemen of the twenty-five corporations can only, in that in which they were first made free; and the elected are those alone who at that time followed the business, or followed it five years, or served an apprenticeship to it; and the corporation of merchants is the only one exempted from these regulations.

The sheriffs, sheriffs peers, and the 96 freemen, name eight persons who are freemen, each worth, in real or personal property, L. 2000, and above all their just debts, two of whom are to be chosen for that office by the lord mayor and aldermen, or the usual quorum of them. In the event of death, or resignation, four freemen are to be named in the same form, for the choice of one to fill the vacancy.

The lord mayor and the aldermen, or the usual quorum of them, send the name of the alderman chosen by them to serve the office for the ensuing year, to the sheriffs' assembly for their approbation, without which no person is capable of serving that office. In the failure of either assembly doing their duty, the other is enabled, by the statute, to make a valid election. All election is by ballot, and no person chosen lord mayor, sheriff, recorder, or town-clerk, is capable of serving that office until he be approved of by the chief governor and the privy council.
The revenue of the city arises from the rents of the landed estate, a great part of which had been let when the acreable value was very low: from tolls received on the commodities that come into the city for sale, or in bulk for private use: from the fishery of the river of Dublin: from fees of admission into the corporation: from the fees for the administration of justice, for ascertaining the weight of commodities, and their quality.

The ground rent of the streets in the city varies from 5s. to 9s. sterling per foot. The usual breadth is from 21 to 25 feet in front, and 125 feet in depth. The building of a good house of five stories, including the cellar, with suitable out-offices, cost L1,500; and of course it is valued at a rent in proportion to the expenditure of L8 per cent.

The taxes of a house now described amount to L4.5 this year (1814). The window tax is doubled; and for 28 windows is L20, 9s. 6d. Irish; besides the heavy taxes that have been charged for the several public buildings lately erected. The city tenures are seldom of a longer duration than the probable existence of the buildings erected in them: this should induce the legislature to empower the commissioners of these improvements to borrow money by debenture, to be replaced by a moderate tax, which would in time repay the principal borrowed, and all its interest. This observation arises from the oppression felt by the operation of the act for making public sewers: the commissioners were empowered to levy the whole sum from the tenant in possession, without any regard to his interest in the premises.

The prisons have all been rebuilt within these thirty years. The great felon's prison cost L16,000. It is quadrangular, and the longest side is 170 feet, and the other 120 feet. It consists of four stories, including the cellarage, where those under sentence of death are lodged. The angles are towers for recesses, which are so badly arranged, that the foul air is forced out on every change of weather, through the wards of the prison. This circumstance, and the conviction that the court-yard should be left open on one side for ventilation, will, it is hoped, influence the government to examine this matter fully. There is an allowance of food and bedding fairly distributed to the prisoners, under the inspection of the chaplains.

The Black Rock on the south side of the Bay, and Clontarf on the north side, are bathing towns well built. They have the accommodation of regular stages; also of a great number of carriages at the stand always ready, and of a twopenny post. See Ireland. (d. f.)

DUBOISIA, a genus of plants of the class Dicydynamia, and order Angiosperma. See Brown's Prodromus Plant. Nov. Holl. 6th. p. 448; and Botany, p. 257.

DUCK. See Ornithology.

DUCTILITY, is the property possessed by metallic bodies, of being drawn out to a fine wire.

The ductility of a metallic wire is therefore the resistance which it opposes to a force acting in the direction of its length, and is measured by the weight which is necessary to break a wire of a given thickness.

The malleability of metallic bodies is the property which they possess of being extended, either by pressure, or by the repeated blows of a hammer, into flat plates or leaves, without having their texture injured. The word tenacity is the general term which includes both the properties of malleability and ductility.

The following Table contains the metals arranged as nearly as can be done in the order of their malleability:

<table>

DUEL, (bellum inter duos,) a single combat, at a time and place appointed, in consequence of a challenge. It must be premeditated, otherwise it is called a rencounter.

The practice of deciding differences by single combat has prevailed from the earliest ages of the world. Single combat prevailed from the earliest times. Of this we have many striking instances, both in sacred and profane history. But these combats were very different from the duel, as it is now practised. In the ancient history of civilized nations, such a species of warfare is not to be found. It is a peculiarity of modern times.

The origin of the duel is to be sought in the superstitions customs of the Scandinavians and other northern nations. Among all such nations, courage seems to have been the ruling principle. This principle, impatient of the forms of law, impelled them to avenge their own wrongs at the point of the sword; and whoever declined to do so, was branded with the appellation of cowardice, and on that account looked upon as infamous. Patricius informs us, that it was the practice of the northern nations, from the earliest ages, to decide their disputes with arms.

This practice was intimately connected with their notions of religion. The belief of a Providence seems to be interwoven with the principles of the human constitution, since it has clearly manifested itself in every age of the world. But till revelation threw light upon this interesting doctrine, it was the general opinion, that adequate rewards and punishments were distributed in the present life. The prosperous were regarded as the objects of the divine favour, while the afflicted were looked upon as suffering the punishment of their crimes. Hence the single combat was viewed as a direct appeal to heaven, and he on whose side victory declared was believed to have the juster cause. It was employed
DUEL.

In several countries, too, to avoid the shedding of blood, the accused were allowed to clear themselves by oath. This oath, in important cases, was made to extend to a number of witnesses, who were all obliged to swear to the innocence of the accused person. In this way, considerable care was taken to arrive at the truth. But as the most turbulent and wicked are always least restrained by the sanctions of religion, the guilty were often led to vindicate themselves by swearing falsely.

Opinion of the German nations,

Tacitus informs us, that when one German nation intended to declare war against another, they endeavoured to take some person prisoner, whom they obliged to fight with one of their people; and by the event of this combat they judged of the success of the war. They considered it, whatever it was, as a decree of heaven, ever attentive to punish the guilty.

This summary mode of obtaining justice accorded with the character of the people among whom it prevailed; and having once gained ground, it was reduced to regular form, and made part of the legal jurisprudence. Magistrates appointed the place where the combatants were to fight, the weapons they were to employ, and all the circumstances connected with it. Both the accuser and accused gave pledges to the judges that they would abide by the issue of the trial. And so far did the custom prevail among the Germans, Danes, and Franks, that none were exempted from it but women, sick people, cripples, and such as were under 21 years of age, or above 60. Even ecclesiastics, priests, and monks, were obliged to find champions to fight in their stead. The punishment of the vanquished was either death, or mutilation of members, according to the circumstances of the case.

This practice, originally adopted for discovering truth, and preventing perjury, gradually degenerated into a species of self-avenging power, not only tacitly permitted, but publicly authorised; and its laws and regulations were accurately defined in most kingdoms of Europe.

Under the feudal system, the duel was warmly patronised. The haughty barons, regardless of the principles of law and justice, considered their sword as the avenger of their wrongs, and disclaimed to submit to any thing but their own strength and prowess for obtaining satisfaction. They were ignorant and untractable. They were fierce, cruel, and oppressive. The administration of public justice was impeded by the force of private animosities, while every domineering chief not only made himself the determiner of his own cause, but claimed the sole power of judgment over his vassals. These he protected and defended in all their depredations on others, but held them himself in the most absolute slavery. A powerful baron seldom appeared abroad in those times, but with the view of plunder or freebooty, or to execute some purpose of revenge or lust. And having accomplished his purpose, he retired within the gloom and entrenchment of his impregnable castle, which was equally fortified against the admission of his rival baron, or his lawful sovereign.

These evils gradually arose to an alarming height. Every kingdom was distracted by the private quarrels and petty wars of a lawless aristocracy. War and the duel were the ruling passions to which all considerations of religion, justice, and humanity, were made to bend. In such a state of society, some possessed of more enlightened views and better principles, endeavoured to direct and control this torrent of unprincipled courage and military violence. With this view, they formed themselves into societies for the relief of injured innocence and distressed virtue, for the redress of oppressions and grievances, for the protection of the weak and defenceless, for the correction of abuses, and the promotion of the public good.

Hence originated chivalry and knight-errantry, which at the same time modified and increased the practice of duelling. Chivalry certainly tended much to soften the manners of the age in which it originated. It not only taught mankind to carry the civilities of peace into the operations of war, and to mingle politeness with the use of the sword,—it roused the soul from its lethargy, invigorated the human character, and produced exploits which have been the admiration of succeeding ages. But while it produced these effects, it gave birth to punctilious refinement, and sowed the first seeds of that fantastic honour, the bitterness of whose fruits are still felt in the modern duel. Every youth of distinction, being trained in this school of honour, was taught to consider military fame and personal valour as almost the only sources of glory.

But to preserve this valour from degenerating into brutal force, a new code of punctilious and refined observations was introduced, on the principles of which the laws of modern honour are founded. The grounds also of the duel or single combat were widely extended. Persons invested with the honours of knighthood did not fight out of malice or revenge, but to signalize their bravery in the protection of the defenceless, and in maintaining the glory of their respective nations. At all banquets of consequence, feats of personal valour were exhibited. Tournaments and tournaments were the common sports and pastimes of the age; and those combats were often countenanced by the presence of the prince and his whole court. When Edward III. and his gallant son invited knights of all nations to be present at these tournaments, when the most distinguished females graced them with their presence, and the champions were eager to lay the trophies of their victory at the feet of those they loved, no wonder that they were urged on to the most remarkable displays of valour.

These tournaments continued long in high estimation. But the death of Henry II. who was killed in one of them, gave a death-blow to their progress; and the renown of chivalry fell with that monarch to rise no more, but in the tales of romance. The duel, however, which had grown up along with it, was not so easily stopped. It had arisen to such a height, as to call loudly for the interference of public authority to check its extravagance. The challenge of Francis I. to his rival, the Emperor Charles V. countenanced this practice. From that time, the single combat on private and personal injuries increased with rapidity. An over-refined sense of honour was ready to construe every thing into an affront. An unguarded word, a haughty look, and a disdainful carriage, were often productive of the most fatal consequences.

From this period we may date the origin of the modern duel. The subjects of Francis, fierce in their courage, lofty in their sentiments, and punctilious in their manners, now indulged their native propensity to the single combat, under the countenance and even injunction of their monarch, who left it to his successors to feel the weight of the growing evil.

As the practice of duelling nowhere rose to a greater height than in France, so in no country were more
Duel.

Duels still permitted in Malta.

Edict of Louis XIV.

Means employed by Henry IV. to prevent it.

First royal prohibition of duels in France.

Duel.

179.

But we Popes, was the council held in 855, Nicholas I. and last of all, the council of Trent in Session xxv. chap. 19. This council terms it a detestable custom, introduced by the devil for the destruction both of body and soul, excommunicating not only all those who fought themselves, but all their associates, and even the spectators of the battle.

Kings and princes also attempted to abolish it in their dominions. Philip the Fair, at the close of the 13th century, wished to suppress it; but the spirit of the times so much opposed his good intentions, that he could effect nothing more than publish an edict, by which nothing was to be brought to that issue, which could be determined otherwise. This edict was but little regarded. Things went on as before till the time of Henry II. when one of his favourites, having fallen in a duel in his own presence, he took an oath never to allow any duel during his reign, and he published an edict to that effect. This seems to have been the first royal prohibition of duels in France. But notions of punctual honour had prevailed so much, that it was doubtful whether this prohibition did not serve to increase the number of private duels. For before this reign, trials of this nature were only permitted on serious occasions, or in instances of great personal offence, and those who dared to fight without obtaining the royal permission were deemed guilty of high treason. But as no such consent was now to be obtained, every man conceived himself a judge of his own case, and, dreading the least imputation of his personal courage, was more ready to stretch the usual points of honour than to curtail them. Honour, too, is of such a delicate and tender nature, as to exert itself most in satisfying those points which are not of strict legal obligation.

The parliament of Paris, June 26, 1599, declares all those who have any way assisted or been present at duels held for such unlawful prosecution of quarrels, rebels to his majesty, transgressors of the law, and disturbers of the public peace. In consequence of which, Henry IV. in his edict at Blois 1602, mentions that the disorders arising from the custom of fighting duels for the reparation of honour, were so great, and so much Christian blood was spilt by them, that he could not judge himself worthy of swaying the sceptre, if he did not put a stop to that abuse. During the first eighteen years of his reign, not fewer than 4000 gentlemen are said to have perished by the duel in France. In June 1609, besides the penalties already imposed, he ordained punishment for all who were any way concerned in duelling, not only the principals, seconds, and carriers of challenges, or offensive and provoking words, but for such as came as spectators, without intention of fighting, and even for those also, who, coming accidentally, did not endeavour to prevent the effusion of blood; and that by death, confiscation of goods, loss or suspension of places, fines, imprisonment, degradation from honour, and infamy, according to the share they had in the murder.

In the beginning of the reign of Louis XIII. to elude the force of former edicts, it was attempted to class duels under the head of accidental encounters, upon the pretext that no challenge was previously given. This induced that prince to extend the former edicts respecting duels to encounters also. The practice, however, went on, in spite of every attempt to put a stop to it. Edicts were passed, every one severer than another, but the evil continued to gain ground. There is scarce any Frenchman, says Lord Herbert, deemed worth looking on, who has not slain his man in a duel.

Louis XIV. set himself to oppose this bloody practice, and issued many edicts to that purpose. In particular, he published a famous one in 1679, which did more to restrain duelling than all the attempts of his predecessors put together. A solemn agreement entered into by many of the principal nobility and gentry of the kingdom, contributed greatly to this effect; and also his own firmness in refusing all solicitations in behalf of offenders. To check this alarming evil seems to have been one of the chief wishes of his heart, since in his last will he particularly recommends to his successor the care of his edict against duels. From that time they have been much less frequent than before.

In 1712, Augustus, King of Poland, published a severe edict against duelling, consisting of no less than 62 articles. And now, perhaps Malta is the only country in the world where the duel is permitted by law. In Bydalone's Tour, we have the following account of it.

"As their whole establishment is originally founded on wild and romantic principles of chivalry, they have ever found it too inconsistent with these principles to abolish duelling; but they have laid it under such restrictions as greatly to lessen its danger. These are curious enough. The duellists are obliged to decide their quarrel in one particular street of the city, and if they presume to fight any where else, they are liable to the rigour of the law. But what is not less singular, and much more in their favour, they are obliged, under the most severe penalties, to put up their swords when ordered to do so by a woman, a priest, or a knight. Under these limitations, in the midst of a great city, one would imagine it almost impossible that a duel could ever end in blood. However, this is not the case. A cross is always painted on the wall opposite to the spot where a knight has been killed, in commemoration of his fall. We counted about twenty of these crosses."

Though duelling was never carried to such an extent in this island as in France, in both kingdoms it originated from the same source, and owed its progress to the same causes. The judicial combat prevailed much in England, especially about the time of Edward III., and made a part of the law of the land. So late as the year 1571, in the reign of Elizabeth, a demand was made for a decision by judicial combat, concerning the right of some manorial lands in the small isle of Hartie, near the isle of Speey, Kent. A proceeding was instituted in the Court of Common Pleas against the holder of the lands. The defendant demanded leave to maintain his possession by the duel; the petitioners accepted the challenge, and the whole bench of lawyers was put into confusion how to act upon this appeal. This proves that the judicial combat was still held to be a legal mode of proceeding when both parties were agreed, though it had fallen much into disuse. The law courts do not seem to have had a power of refusal. Accordingly, champions were immediately chosen by each party to decide the combat, and all the requisite forms were adjusted; but the queen, anxious to avoid bloodshed, procured a composition between the parties; at the same time, that the formalities of the law might be gone through, she permitted the duel to proceed. According to the day set, the Justices of the Common Pleas, the counsellors and lawyers, went down to Tothil Fields to be umpires of the contest; and the customary formalities were carefully attended to; but, as it had been previously agreed, the parties did not appear to acknowledge their respec-
DUEL

Duel.

The private duel gains ground.

Attempts made to suppress it.

Law in England respecting it.

In Scotland, duelling had not only been permitted, but also in civil causes. Accordingly duelling is mentioned as one of the general forms and manners of probation used in courts. But the Scottish legislature began to recede from this savage jurisprudence, so early as the reign of Alexander II. when it was ordained that, "in time coming, no judgment or sentence shall be given by water, or in air, as has been used in all times." Single combat maintained its ground somewhat longer; and, in the reign of Robert III. four things were necessary to render duelling legal, 1st, That the crime should be capital. 2d, That it should be certain the crime was committed. 3d, That the accused should be rendered infamous by it. 4th, It must not be capable of proof by witnesses. Judicial combat at length fell into total disuse, with the progressive dawning of a more enlightened jurisprudence; and, for ages, duelling has been no otherwise recognised than as a heinous offence against morality and religion, which it has been thought proper to restrain by the severest sanctions.

If the parties actually fight, and one of them be killed, whatever may have been the provocation, or however fairly the parties may have conducted themselves, this is murder, both by the law of Scotland and England; for the circumstances of sudden provocation, which lower the offence to the denomination of manslaughter, are not understood, by the law of either country, to apply to those who meet avowedly with an intent to murder.

Farther, the mere act of engaging in a duel, whether the parties receive any wound or not, is made capital by the statute 1600, chap. xii. and the provoker is to be punished by a more ignominious death than the other, at the pleasure of the sovereign. This statute makes no mention of seconds; but the subsequent one of King William enactis, that whosoever, principal or second, or other interposed person, gives a challenge to fight a duel or single combat, or whosoever accepts the same; or whosoever, either principal or second, on either side, engages therein, albeit no fighting ensued, shall be punished by the pain of banishment, and the exchequer of moveables, without prejudice to the act already made against the fighting of duels. Both these statutes have lately been declared, by the Court of Justice, to be still in force. There have not, however, been many prosecutions on this statute, which must be considered to be a rigorous law. And Mr Hume observes, he could not find in the records more than two instances of a conviction upon it.

This statute applies only to a serious proposal and settlement of a combat. Ambiguous hints, or innuendos, on the one hand, or on the other, mere verba jactantia; passionate words of defiance, uttered face to face, and only tending to a challenge, are punished arbitrarily at common law, but not by the statutory pains. For example, in the course of a scuffle, one of the persons engaged in it, besides other abuse, calling to another of them to get a sword, and give him satisfaction, was not found a relevant charge under this statute.

Such is the history of duelling, and such the law respecting it. Duelling is founded upon the principles of honour. These principles, when properly directed, exalt and adorn the character, and animate us in the pursuit of what is noble and excellent. But, like all the other principles of our nature, when not properly directed, they are productive of the worst consequences. The object which the duellist proposes is altogether of a personal nature, being either to gratify some passion, which every good man ought to avoid, or to avoid the imputation of cowardice, of which, perhaps, he was never suspected. His object therefore is selfish; and the means by which he attains this object are contrary to law, reason, and religion. He takes the law, indeed, in his own hand, and acts as judge in his own cause. On account of some unguarded word, or some trifling offence, he wantonly risks his own life, and involves, perhaps in wretchedness, a wife and family who depend upon him for subsistence. Religion enjoins forgiveness of injuries,—the duellist thinks only of revenge. Religion recommends patience and forbearance,—the duellist declares, that he who does not resent his own wrongs, is not fit to live in society. Humility is a fundamental principle of the Christian religion,—duelling is supported and nourished by pride: for honour, in the fashionable sense of the word, is nothing else than pride: modified by certain rules.

Hence this practice has ever been reproved by all Sully's wise and good men. The Duc de Sully, one of the first generals of his own or any other age, has transmitted to posterity his testimony against it, in the following pointed language, "That," said he, "which arms us against our friends or countrymen, in contempl..."
of all laws as well divine as human, is but a brutal fierceness, madness, and real pusillanimity." Upon this subject Paley has some excellent observations. "The law of honour is a system of rules constructed by people of fashion, and calculated to facilitate their intercourse with one another, and for no other purpose. It prescribes and regulates the duties between, omitting such as relate to the supreme Being, as well as those which we owe to our inferiors. For which reason, profaneness, neglect of public worship, or private devotion, cruelty to servants, rigorous treatment of tenants, or other dependents, want of charity to the poor, injury done to tradesmen by insolencies, or delay of payment, with numberless examples of the same kind, are accounted no breaches of honour, because that man is not in less agreeable companion for these vices, nor the worse to deal with in those concerns, which are usually transacted between one gentleman and another. Again, the law of honour being constituted by men occupied in the pursuit of pleasure, and for the mutual convenience of such men, will be found, as might be expected from the character and design of the law-makers, to be, in most instances, favourable to the licentious indulgence of the natural passions. Thus it allows of fornication, adultery, drunkenness, prodigality, duelling, and revenge in the extreme, and lays no stress upon the virtues opposite to these."

In the late case of Lieutenant Blundell, who fell in a duel, in the Isle of Wight, not only his antagonist, and his second, but also two others who were deemed accessories, were all four convicted of murder at the Hampshire assizes, and sentenced to die. The royal pardon, however, was obtained for them; but being officers in the army, they were soon afterwards dismissed the service. And the commander in chief, in his general orders, concluded by hoping, "that it will give an useful and impressive lesson to the young officers of the army, and a warning to them of the fatal consequences of allowing themselves to be misled by erroneous notions and false principles of honour, which, when rightly understood, and leading to its legitimate object, is the brightest gem in the character of a soldier."

Dueling has no doubt contributed to soften the rude manners of former times, and to promote that respectful and delicate attention to one another, which distinguishes the inhabitants of modern Europe from the most civilized nations of antiquity. But in checking ferocity, it gave birth to punctilious refinement, and solved the first seeds of that fantastic honour, the bitter fruits of which have been so extensively felt. Chivalry also had a very considerable influence in polishing the manners of a less refined age. In the progress of society, however, it passed away, and gave place to a more sober mode of thinking and of acting; but duelling still prevails to testify, how weak are the restraints of religion and of law, when opposed to the domineering influence of fashion.

This custom originating in a period of ignorance and superstition, has maintained its ground amidst all the improvements of society, and has come down to our times with unabated force. This circumstance is very much owing to the laws which have been passed against it not being carried into effect. When Louis XIV. alarmed at the extent of this growing evil, set himself strenuously to oppose it, it is wonderful with how much success his exertions were attended. And were the governments of Europe now equally strict in enforcing the laws against it, there is every reason to think that the practice might soon be abolished. But when laws are passed and not executed, instead of deterring, they serve rather to encourage offenders. The trifling damages too that are frequently recovered in prosecutions for this offence, serve only to make the sufferers ridiculous.

The most effectual plan for putting a stop to this evil, would certainly be to enforce the laws that are now in existence against it. But, perhaps, something more than this might be done. A court of honour might be established, especially for the army, where the point of honour is cultivated with exquisite attention and refinement, with a power of adjudging those submissions and acknowledgments, which it generally the object of a challenge to obtain. Similar institutions might be formed for other professions, which might go to eradicate this invidious disorder of modern times.

There is some probability, however, that the evil may correct itself. If it descend from the higher to the lower orders, and become common among all classes of the community, the great may be led to renounce a practice which can no longer be regarded as honourable. And if it lose its sanction and authority, there is every reason to think that it will gradually be abolished. See Moore on Duelling. Cockburn's History of Duelling. An account of the Abolishing of Duels in France. Montesquieu's Spirit of Laws, vol. ii. (n)

DVINA, a river of Russia, and one of the largest in Europe. It is navigable, and a great trade is carried on by it and its tributary streams with Archangel. It falls into the White Sea by five different channels, only two of which are navigable. The following rivers fall into the Dvina:

The Pinaq, down which a great quantity of timber is floated.

The Vitzegda, which receives the northern Keltma, a river which the Russian government proposed to unite with a southern river of the same name that joins the Kama. A canal was actually begun, but it was discontinued upon the breaking out of the war.

The Uga, and the Lower Souchona, are two of the principal branches of the Dvina. Great quantities of grain, and other merchandise, are conveyed down the Lower Souchona, from Vologda and its neighbourhood to Archangel. It rises in the lake Koubenska, by means of which it is proposed to open a communication between the Souchona and the river Seleksa.

The Russian government has proposed to unite the Dvina with the Niemen, by means of the rivers Nevesha and Lavenna; and a plan and estimate have been given in by General de Witt. This plan would be of the greatest advantage to all the adjacent country, but particularly to Livonia, Lithuania, Courland, and the country beyond the Oginsky canal. The productions of these fertile regions, instead of being carried into the Prussian ports of Königsberg, Memel, Pillau, &c. would be conveyed to Riga, Kofina, &c. and the native merchant would thus derive all the advantage which accrues from the sale of his goods in his own country. See the Report of the Board of Russian Engineers on the state of the internal Navigation of Russia, in Clarke's Travels, vol. i. Appendix, No. viii. (s)

DULCIANA, stop, in music, is one of the ranges of metal pipes in a organ, long and slender, of a peculiar sweetness of tone, which Mr Stetszler introduced into the choir organ as a sole reed stop. It is tuned in unison with the diapasons, but has less compass than them, descending only to G-gomut. It is a stop that usually stands well in tune. (t)
DUMB AND DEAF.

There is nothing which relates to the intellectual acquirements of early life more certain, than that the noblest of them all, the acquisition of Vocal Speech, depends entirely on the sense of Hearing. The same early lesson of experience which teaches the child, that, by a certain voluntary effort, he can extend his arm, informs him also, that, by a similar exertion of his will, he can produce certain vocal sounds. He endeavours to imitate the words that are spoken by those around him. His first attempts are unsuccessful, because his memory is yet feeble; and because his voluntary actions, in this instance, just as in his first amusing struggles to gain that erect position by which man is distinguished, are irregular and unsure. But repetition brings continual improvement; age develops the other faculties of the mind; and without the least regard to those vibrations in his throat, or those motions of his tongue and lips, by which his purpose is accomplished, he goes on, from indistinct prattling, to the acquisition of clear and perfect Speech, regulated solely by the Ear.

To those, however, who have been born Deaf, or who have been affected with incurable Deafness before articulation had been attained, or sufficiently impressed on the memory, it is obvious, that this natural guide to the acquisition of Speech is utterly denied; and so obscure or unattainable does the only other path to the possession of this important faculty seem to such persons, that, when left to themselves, no attempt is ever made by them to gain it. The records of physiology do not present us with a single instance of an individual born Deaf, or deprived of hearing in infancy or childhood, who did not remain Dumb for life; unless cherished and instructed by the philanthropy and ingenuity of some fellow-creature, more happily gifted than himself.

It is to persons in this condition,—to those who are Dumb merely because they are Deaf,—whose organs of Speech are perfect,—whose intellect is good,—and who differ from other individuals only in being incapable of sensations of sound,—that the term Deaf and Dumb or Deaf-mute is applied.

The task of education is never, perhaps, more truly delightful, than when this unfortunate though interesting class of persons are the subjects of it. They unite, in general, to singular steadiness of application, the greatest gentleness and docility; and expressions of counterance, as cheering as they are unequivocal, continually declare the emotions of gratitude with which they receive instruction. It is pleasant to become their pupils in our turn, and to learn of them that natural pantomime by which all their wants are expressed. Copious, however, and significant as that language is, it is necessarily intelligible but to a few; and it is indeed an exciting satisfaction which they seem to feel, when they are taught to exchange it for the more powerful medium of words; and are thus, as it were, enabled, to command the thoughts of all mankind. We see their happiness increasing with their knowledge; and when the sublimity of nature is first unfolded to their opening minds, and we mark the tear starting into their eyes, we cannot but participate in their noble pleasure, and rejoice that such emotions can be theirs.

In the present article, we propose to state the general principles according to which the Education of the Deaf and Dumb ought to be conducted; avoiding all those minute details which could be of no interest to the general reader; and which even to those who mean to occupy themselves practically with this species of instruction, could be of little advantage; since they are of a nature to suggest themselves to any intelligent teacher, almost as soon as they could be taught.

We suppose the education of the Deaf and Dumb pupil to commence at the age of eight years. By this period, children who enjoy the sense of hearing, have always acquired the full command of their organs of Speech; they have learnt the meaning and application of several hundreds of words; and to the stock of knowledge, which youthful curiosity has stimulated them to obtain, by their own personal observation, within their own limited sphere, they have been enabled to make a most important addition, from the verbal information of others. The business, therefore, of their early education, consists, merely, in making them acquainted with the written and printed characters of those words, whose pronunciation is already familiar to them; and by an analysis of these, pointing out to them all the visible signs of those simple articulate sounds, out of which the whole of Speech is constructed. After this, reading presents them with abundance of new words; and should any of these not be susceptible of explanation by terms already known, they are gradually enabled to collect their meaning, by frequent and attentive observation of the manner in which they are used, in conversation, by others. Nor are their lessons in language confined to the tasks of the school; at meals, at play, abroad, at home, everywhere, they are continually acquiring from the speech of their seniors, either new terms, or new or more correct methods of employing the vocabulary which they already possess.

But the task which the Deaf and Dumb have to enter upon, is much more complicated and difficult. Ignorant of every part of that system of signs, which mankind have invented for the communication of thought, they have to be instructed, not merely in those written characters which are the representatives of words; but in the method of articulating the words themselves, and of distinguishing them when articulated by others; and in the precise meaning which each of them is intended to convey. Many circumstances, too, combine, to render this process tedious. We cannot, in their case, it is obvious, define one word by another; but the signification of each must be taught, either by a direct appeal to things themselves, or the pictures of things; or by the language of gesticulation and natural signs. The narrow stock of knowledge which they bring with them, when compared with those who enjoy the sense of hearing, circumscribes greatly that field of illustration, which is required in the early stages of instruction. And what is a less material disadvantage, they are entirely cut off from that constant source of new ideas, as well as new words, which other children enjoy in their intercourse with society.

Experience, however, has shewn, that all these difficulties may be overcome by perseverance; and in pointing out what appear to us to be the best means of attaining this important object, we shall refer our observations to...
the four following heads, viz. Writing, Manual Speech or Daetaylogy, Vocal Speech, and the Explanation of the Meaning of Words.

The very first step in the education of the Deaf-mute, is, to teach him to write. Writing is a medium of instruction so necessary, in his situation, that it cannot be too early acquired. No particular directions are requisite for this purpose. It may be taught first on sand with the finger, or on a slate with the pencil, in the usual way, and afterwards on paper with pen and ink. Comparatively little attention, however, need be paid at the commencement to the nicety with which the letters are traced. The chief object is to enable the pupil to connect letters together with legible distinctness, as speedily as possible; and, this done, practice will gradually give the manipulation its necessary accuracy and precision.

Along with Writing, the pupil is to be taught the method of representing letters and words by the fingers, or what has been called Daetaylogy. This is an easy task. The Manual Alphabet, which is represented in Plate CCXLI. seems to us very well adapted for the purpose. It is that which is taught by Dr Watson, (Instruction of the Deaf and Dumb, &c. 8vo. Lond. 1809); and which, we should conceive, is both more easily practised, and less liable to confusion, than the one employed by Sabelcard, in which only one hand is employed. (Cours d'Instruction d'un Sourd-Muet de Naissance, &c. 8vo. Paris, 2d edit. 1803.)

The uses of this Manual Speech are obvious. It is much more expeditious than writing; it can be practised in any situation, and without any such implements as slate, or pencil or paper; it admits of being addressed to several at a time; and, what is a most important advantage, it affords a medium of communication between persons who are placed at a considerable distance from each other. Dr Watson, too, assures us, that it is intelligible to the touch, as well as to the sight, and consequently may be used in the dark (Work quoted above, p. 121.) It is remarkable, that even those deaf and dumb pupils who have been taught to speak vocally, always employ this Manual language alone, in addressing each other. Nor is it to be regarded merely as an instrument of education. The Deaf and Dumb, in their after intercourse with the world, will meet with many persons who have taught themselves to speak on the fingers, merely as an amusement, and not from any defect in their organs of hearing or articulation. With such persons, therefore, they may often enjoy the pleasure of conversation in circumstances calculated to render Vocal Speech both difficult and embarrassing.

After the pupil has made a little progress in Writing and Daetaylogy, the more laborious task may be entered upon, of teaching him Vocal Speech.

This, unquestionably, is the most extraordinary accomplishment which it is possible for a Deaf and Dumb person to acquire. That it should be possible to instruct such a person, through the medium of writing, as fully, in every department of human knowledge, as those who enjoy the sense of hearing, does not appear in the slightest degree remarkable; for it is not more difficult to associate our ideas with a system of visible than of audible signs. But that he should be capable of learning both to emit sounds and to articulate them, merely by observing with his organs of touch and sight, those minute vibrations of the throat, and those rapid and delicate motions of the parts belonging to the mouth, which accompany the speech of others, is a thing so singular, that, previously to experiment, we should suppose it almost impossible. Yet it is curious to remark, that this seems to have been a chief object even with those to whom the idea of instructing the Deaf and Dumb first occurred; and that the earliest attempts which are recorded to have been made to teach Deaf-mutes to speak, appear to have been attended with complete success. In truth, all those who have enjoyed much experience in the education of the Deaf and Dumb, agree in declaring, that this is a department of it, in which any one cannot fail to succeed, who resolves to bestow sufficient time and patience on the task; and who has good sense and good nature enough to encourage, by kind arts, the perseverance of his pupil.

In attending particularly to the phenomena of Speech, two things present themselves for consideration: in the first place, the various Sounds which compose it; and secondly, different Modes in which these Sounds are begun or ended.

The Sounds which enter into the composition of Speech may be arranged into two classes; and these shall distinguish by the terms Laryngeal and Oral.

Laryngeal sounds are those which are produced entirely by the larynx. Such, for example, are the sounds of the letters a, o, l, n. A distinction exists among these, which, of course, is familiar to every one; namely, some of them are Vocal sounds, or constitute what is called voice; others are Whispering sounds, and occur only in the whisper.

Both these kinds of sounds, without doubt, depend on vibrations produced in the expired air during its passage through the larynx; though it is not easy to ascertain the causes of the difference betwixt them. We may remark, however, that Vocal sounds are susceptible, not only of various degrees of strength or loudness, according to the different degrees of force with which the air is expelled from the lungs; but also of the greatest variations in tone, from changes in the dimensions of the windpipe, or varieties in the shape or size of the rima of the glottis. Whispering sounds, on the other hand, are susceptible of changes in point of loudness alone, without the slightest perceptible variety in the quality of tone; and we are rather inclined to think, that the vibrations on which they depend, are produced, not more by the aperture between the vocal chords, than by the other parts of the larynx. What is of more importance, however, to our present purpose to be known, is, that during the production of every Vocal sound, a distinct vibration may be felt externally, by applying the fingers to that prominence on the fore and upper part of the neck which corresponds to the larynx, and which is often denominated the pomum adami. But in the production of a Whispering sound, no such vibration can be perceived.

It is not, however, by any changes of loudness or How diverse tone taking place in the larynx, that the Laryngeal sounds employed in Speech are so much diversified; but by differences in what we call, physiologically, their expression, and which depend on certain configurations voluntarily given to the parts of the face and mouth, while the sounds are emitting from the larynx. We are accustomed, in fact, to observe a very great uniformity in the tones and intensity of the sounds we employ in Speech; but were we even disposed to introduce more variety in these qualities, still the Sounds would not undergo any altera-
Dumb and Deaf.

Dumb and Deaf.

The expression of this sound depends on the same parts as the former; only, the surface of the tongue is brought a little nearer to the roof of the mouth, so that the channel through which the air passes is smaller.

6. The sound expressed by the letters $t$ in $t$ all, by $L$.

There are twenty-one Laryngeal sounds, all differing in expression from each other, employed in the English language. We shall consider each of these separately.

1. The sound expressed by the letter $a$ in the words art and at.

In the former of these words, the sound is expressed much more slowly than in the latter; in the one, therefore, it is said to be long, and in the other short. A long sound is usually pointed out by a straight line drawn above the letters representing it, thus, $\text{art}$; and a short one, by a curved line, thus, $\text{at}$. We shall employ these marks for the sake of brevity, in our future illustrations.

In this sound the breath escapes entirely by the mouth, so that it cannot be pronounced when the lips are shut. Its expression depends on a particular position of the back part of the tongue and the velum of the palate.

We will not attempt to describe this; but any one may observe it in himself by means of a mirror. The expression suffers no change, either by varying the position of the lips, or the tongue, or by shutting the nostrils.

2. The sound which is expressed by the letter $a$ in the word hall, by au in taught, by o in hot, and by ou in sought.

The expression of this sound depends on the same parts of the tongue and jaws as the former; only the root of the tongue is a little more arched upwards.

3. The sound expressed by $o$ in note, and by $oo$ in boot.

To give this sound its expression, the back part of the tongue is still a little more arched upwards than in the former.

The expression is a good deal modified by varying the size of the orifice of the lips. In common conversation, it is always pronounced with a small opening of the lips, which gives it a much more hollow expression, than when the mouth is open, as during laughing; and we may observe, that the orifice is always less than during the utterance of either of the two preceding sounds.

4. The sound expressed by $a$ in rare, by $ai$ in wait, by $ay$ in day, by $e$ in shell, by $ea$ in pier, and by $ei$ in feign.

In this sound, as well as in the three preceding, the breath escapes entirely by the mouth. The edge of the tongue on each side is brought into contact with the teeth of the upper jaw, as far forwards as the small grinders; its upper surface is formed into an arch, corresponding to the roof of the mouth, but separated to a certain distance from it; and in the channel thus formed, the air passes forwards, and escapes between the tip of the tongue and the fore-teeth of the upper jaw.

The expression is not altered by shutting the nostrils, nor by varying the relative position of the jaws, nor by changing the dimensions of the orifice of the lips, provided they be not entirely shut.

5. The sound expressed by the letter $a$ in pole, by $ai$ in fail, and by $e$ in their or there.

In this sound, the velum of the palate is so raised as to shut up completely the orifices leading from the throat to the nose; the breath, therefore, passes wholly into the mouth. But the expression of the sound depends entirely on the lips being shut; it cannot be pronounced at all with the lips open. Now, as the air which has been excited into vibrations in its passage through the larynx, is afterwards, in this case, urged by the muscles of expiration, entirely into the mouth, none escaping by the nose; and, as its escape from the mouth is also prevented by the lips being shut, the mouth must very soon be filled with it, and then, of course, the sound will cease, expiration being no longer possible. Accordingly, we observe, that the sound of $b$ is one, upon which we can hardly dwell beyond two seconds.

The situation of the tongue does not much affect the
expression of this sound, otherwise than in increasing its duration and its hollowness, when placed so as to enlarge the cavity of the mouth, and in producing the reverse effect, when in an opposite position. The sound is also prolonged, and rendered more hollow, when we permit the inflation of the cheeks, for an obvious reason; but, in general, this inflation is prevented by muscular actions, simultaneous with those which shut the lips. The position of the jaws does not modify the expression.

11. The sound expressed by the letter d, in day, sad, above.

In this sound, as in the former, the pharyngeal orifices of the nose are shut up by the velum of the palate; and the breath passes all into the mouth. Its expression depends, however, on a very different situation of parts. The edge of the tongue on each side is applied close to the under surface of the five grinding teeth, and to the inside of the eye-teeth, and then the tip is pressed firmly against the roof of the mouth, immediately above the insertion of the incisors. In this way, a completely close cavity is formed between the upper surface of the tongue and the palate, which receives the air from the larynx, and gives it this peculiar expression called d. When the cavity is filled, the sound, of course, ceases, as in the case of b.

It is easy to see that this expression cannot be affected by shutting the nostrils, or the lips, nor by varying the position of the lower jaw. When the tip of the tongue, however, instead of being applied to the roof of the mouth, is placed under the edges of the front teeth, a peculiar modification of the expression is produced, which is extremely common in the dialects of some parts of Scotland, particularly in that of Aberdeenshire.

12. The sound expressed by the letter g in good, dog, begone.

In this sound, too, the passage from the throat to the nose is stopped. The back part of the tongue is raised up towards the upper part of the velum of the palate, and is then applied to it so closely as to form a small cavity with it, opening downwards towards the larynx. The air passing into this, receives its expression; but as the cavity is small, and consequently soon filled, the sound is one of very short duration; considerably shorter than either d or b.

13. The sound expressed by the letter l in lay, fail, alone.

Here, also, the breath passes out entirely by the mouth. The tip of the tongue is pressed against the roof of the mouth immediately above the insertion of the incisor teeth; and the edge of this organ on each side, is applied only loosely to the inner surface of the remaining teeth of the upper jaw; so that the air escaping between these teeth and the edges of the tongue, receives the expression of l. The sound cannot be pronounced unless the lips are open.

14. The sound expressed by the letter m in man, him, amend.

In this sound, the breath is urged alike towards the mouth and the nose; but it is on that portion of it alone, which is directed towards the mouth, that the expression depends. The tongue lies low, so as to allow a large space for air, between its upper surface, and the roof of the mouth; the jaws are slightly asunder; the lips are shut; and it is the breath pressing against the lips which causes the expression of m.

Although it is necessary for this sound that the lips should be closed, and although the air is thus prevented from escaping by the mouth, yet the free passage for the breath by the nose, enables expiration to go on; and if the nostrils be not stopped, the sound may be continued until the lungs are emptied.

When the nostrils, however, are held fast, no more air can be forced from the chest than is sufficient to fill the mouth and face, and consequently the sound cannot be prolonged beyond a second or two.

15. The sound expressed by the letter n in the words.

Here the expression depends on the cavity of the mouth's being shut, not by the lips, as in the former sound, but by the tongue, which is placed exactly in the same situation as in the pronunciation of the 11th sound. With this difference, all the remarks that have just been made with respect to m, apply equally to n.

16. The sound expressed by the letter r in ran, far, around.

In this sound the breath escapes entirely by the mouth. The edge of the tongue on each side is applied to the under surface of the upper grinders and eye-teeth, as in pronouncing d; but the tip, although rendered pretty firm by muscular contraction, instead of being pressed strongly against the roof the mouth, is merely raised so as to touch gently the part immediately above the insertion of the incisors. The air is then urged towards this point, sets the tip of the tongue into vibration, and escapes around its edge. On this the expression of r depends.

17. The sound expressed by the letter v in vow, have, Laryngeal sound.

The expression of this sound depends on the under lip being brought slightly over the edges of the upper incisor and eye-teeth, but pressing only on the two middle incisors with such force as to prevent the escape of air. The breath, then, urged forward from the throat entirely into the mouth, escapes between the under lip and the edges of the lateral incisors and of the eye-teeth.

18. The sound expressed by the letter s in reason and Laryngeal sound.

In this sound the tongue is placed nearly as in the utterance of the 11th, and the breath escapes entirely between its tip and the roof of the mouth immediately above the incisor teeth. The tip of the tongue, however, is not set into vibration as in that sound, but remains steadily in one situation, and the air in its passage receives merely a sort of hissing expression.

19. The sound expressed by s in pleasure, and by z in azure.

Here the edge of the tongue, on each side, is placed under the inferior surface of the upper grinders; and its anterior part is so applied to the roof of the mouth, as to leave only a small funnel in the middle, which terminates behind the incisor teeth in a slight convexity, caused by the tip of the tongue. All the breath escapes through this passage.

20. The sound expressed by the letters th in thus, Laryngeal sound.

In this sound the margin of the tongue, all round, is placed under the whole of the upper teeth; but it is held but loosely applied to the edges of the incisors, so that the air, urged forward from the throat, escapes between it and these teeth.

21. The sound expressed by the letters ng in long, Laryngeal sound.

This is the only Laryngeal sound in our language, in which the breath escapes entirely by the nose. The instant the nostrils are stopped, the sound ceases. The cause of the expression is easily seen. The velum of the palate is brought a little downwards and forwards, and the posterior part of the tongue a little upwards and backwards; they meet together, and shut up entirely the passage to the mouth.

Oral sounds are such as are not produced in the Larynx, but by some of the parts belonging to the mouth. Like the Laryngeal sounds, they are distinguished from each other by their expression; but they differ from these, on the other hand, in not being susceptible of the slightest variety of tone. They are only five in number.

1. Oral Sound.
   1. The sound expressed by the letter c, in the words cider, nicer; by s in sad, asleep, oats; by sc in scene; and by sch in schism and schedule.
   This sound depends on the breath being made to pass through the mouth, without having undergone any previous vibration in the larynx, while the tongue is placed precisely as in the pronunciation of the 18th laryngeal sound.

2. Oral Sound.
   2. The sound expressed by the letter f, in far, soft, afraid; and by ph, in physic, pneumocon, aphorism.
   This sound is caused by the breath being made to pass out by the mouth, without any previous vibration, while the under lip and upper teeth are exactly in the position necessary for the utterance of the 17th laryngeal sound.

   3. The sound expressed by the letter t in nation; by ch in champaign; by sh in show, ashamed, push.
   This sound depends on the same expression of parts within the mouth as the 19th laryngeal sound, the breath passing through without any previous vibration in the larynx.

   4. The sound expressed by the letters th, in the words thick, athwart, path.
   This sound is caused by the breath passing out between the tongue and upper teeth, placed exactly as in the 20th laryngeal sound, but without any previous vibration in the larynx.

5. Oral Sound.
   5. That-soft but distinct sound accompanying the emission of the breath, which we perceive at the end of the words at, sleep, rock, and which occurs between the two sounds expressed by the letters k and n in the word acknowledge.

Thus we find, that there are 26 distinct sounds, Laryngeal and Oral, employed in the English language.

But it is to be remarked in the next place, that there are certain modes, according to which, if these sounds be either begun or ended, a material alteration will often be produced in their meaning.

These Modes are five in number.

1. Mode.
   The 1st Mode is expressed by the letter c, in coal, acme, siro; and by k in karan, wake, lark.
   This Mode consists in placing the tongue precisely in the same situation as in the pronunciation of the 12th Laryngeal sound, keeping it firmly there, and at the same time urging the breath against it, without any vibration in the larynx.

2. Mode.
   The 2d Mode is marked by the letter b, in hold, unhappy.
   This depends on a short and quick action of the muscles of expiration, by which the breath is urged forward with greater velocity than ordinary, and the sound, at its commencement, receives a sudden sort of impulsion.
   This Mode is never employed to terminate sounds, but only to begin them.

The 3d Mode is marked by the letter p, in pay, uphold, stop.
This Mode is caused by the velum of the palate and the lips being brought into the same situation as in uttering the 10th laryngeal sound, and kept steadily there, and then by the breath's being urged forward against the lips, without suffering any vibration in the larynx.

The 4th Mode is marked by the letter t, in table, tone.

This Mode depends on the breath's being urged forward, without any vibration, into the mouth, the tongue being placed exactly in the same situation as in pronouncing the 11th laryngeal sound.

The 5th Mode is marked by the letter n, in ward, wound.

This Mode consists in urging the lips a little forward, bringing them into contact, so as to leave only a small hole in the middle, and then smartly enlarging that orifice the instant the sound begins. The extent to which the orifice is enlarged, depends on the nature of the sound which is to follow.

These few remarks on the elementary Sounds of our language, are intended chiefly for the instructor of the Deaf and Dumb, not for the pupil himself. We have thought it proper to introduce them here, because the observations on this subject, which prevail in our common works on grammar, seem to us very vague and inaccurate.

The method of procedure in teaching the Deaf-mute to pronounce, in succession, all those sounds which we have just considered, has been described, with so much perspicuity, by one who has had the most ample experience in the art, Dr Watson, that we cannot do better than give it in his own words.

"To effect this," says he, "and to habitude the pupil to associate the sound which he is learning to form, with the figure of the letter which is to be its representative, this is distinctly traced upon paper, or any convenient tablet, and he is made to look at it for a minute or two. He then, if of acute intellect, will look up with some anxiety in his countenance, as if he would ask what he is to do with it. The sound is then slowly and fully pronounced, and the learner made to observe, by his eyes, the position and motion of the external organs of speech, and to feel the vibration of the muscles of the larynx, by placing his finger upon the throat, carefully making him perceive the difference to be felt there between sound and silence. Having made these observations for a minute or two, he will seldom hesitate to attempt an imitation of what he has been observing, and that for the most part successfully. When the contrary is the case, nothing more is necessary than patient and good-natured perseverance; for he perceives that his failure has excited chagrin or disappointment in his teacher, he will make another effort with great reluctance. The sound once acquired, must be practised sufficiently to avoid any danger of losing it; for the greatest care must be taken all through his progress, never to proceed to a new sound till the preceding has become familiar, and unattended with doubt as to the manner of pronouncing it. A contrary practice would lead to endless vexation. A principal requisite is to keep the learner in good humour, and to make him think that he is doing well beyond expectation, and if anything is more discouraging than to put him back,"

On a comparison of the elementary Sounds of our language, and the various Modes of beginning and ending them, with the written characters by which they are represented, it will be easily seen, that our alphabet

Inconvenience from the imperfection of the common alphabet.
Dumb and Deaf.

is extremely imperfect. There is not a distinct letter for each simple sound, and for each mode of beginning and ending; but some sounds and modes are represented by one letter, and others by a combination of letters; sometimes one letter or combination is the mark of several different sounds or modes; and sometimes one sound or mode is expressed by several different letters or combinations. It is this, among other circumstances, which renders the pronouncing dictionary so necessary even to natives of our own country, and which occasions so much difficulty to the foreigner, and to persons in the situation of the deaf and dumb.

With a view not to perplex the pupil in his first lessons in elementary sounds, we would recommend, that only one mode of representing each sound be chosen at the commencement; the various other modes will be pointed out afterwards, when the uses of the different letters of the alphabet are fully exemplified. Thus the letter e may be selected, to represent the 4th Laryngeal sound in the first instance; and it may be afterwards shown, that the same sound is often expressed by a, ai, ay, ea, and ei.

After the scholar has acquired the power of pronouncing the sounds in their separate state, he is next to be instructed in the mode of combining them together into syllables and words. This, upon trial, will be found to be easier than might have been expected.

But the rapidity of the pupil's progress in speaking, and the ultimate proficiency at which he arrives, will be found to vary exceedingly in different cases. There are very few who can be taught to pronounce distinctly all the Laryngeal sounds; one or two of these being almost always unattainable. But it is not always the same sound that presents this difficulty to the learner; in one pupil it is the 1st, in another the 3d, in another the 4th, and so on. Nor is it easy to instuct the Deaf and Dumb in that gentle running of syllables into each other, that modulation of the voice, and that variety of accent and of pause, which are observed in the articulation of perfect and harmonious Speech. On these accounts, their pronunciation is, in general, accompanied with a kind of monotony and broken aspiration; if we may use this expression, which renders it somewhat unpleasing. In some instances, however, these defects exist in a surprisingly small degree; and we have ourselves seen boys who had only begun to articulate about three years before, whose softness and distinctness of utterance were altogether wonderful. At all events, it is gratifying to know, that, however imperfect their speech may be, when compared with that of others, it is, in most instances, sufficiently distinct to be quite intelligible to their friends, and even to strangers, after a little time; and consequently thus answers the leading purpose for which it is intended.

The same lessons by which the Deaf and Dumb are taught to articulate, and the same experience which gives them facility of Speech, instructs and improves them, also, in the power of interpreting by the eye the words of others. The quickness with which they come at last to exercise this faculty, is quite remarkable. "It is truly astonishing," says Dr Watson, "and would hardly be credited by any one who had not seen it, how readily deaf persons, who have themselves been taught to speak, catch words, and even long sentences, from the mouths of those who address them. Yet, in this sort of conversation, it is indispensable that the speech should be immediately directed to the spectator, (we must not call him auditor,) who must have an opportunity of observing every motion of the muscles, (as far as these can be seen externally,) and countenance, in order to make out the discourse. On this account, it is impossible for a deaf person to understand the conversation of a mixed company, a discourse from the pulpit, or a harangue to an assembly, where the speaker does not immediately address him." (Work quoted at p. 180, p. 121.)

We might add some very good observations, to the same purport, from the writings of De L'Epée; but we shall content ourselves, at present, with quoting only a few sentences, in which the Abbé, with characteristic benevolence, pleads for the observation of proper indugences towards the Deaf and Dumb, from all those who wish to address them in Vocal Speech: After stating the precautions to be observed in speaking to them, and remarking, what indeed often surprises the by-standers, that there is no necessity, in doing so, for the least emission of the voice, he observes, Il est vrai que tous ceux qui parlent vis-à-vis des sourds et muets, ne prennent pas toutes les précautions que nous venons d'expliquer, et c'est ce qui fait qu'ils ne sont pas aussi clairement entendus. Si les sourds et muets ne sentent pas autant qu'ils le pourraient, ce n'est pas leur faute, mais celles des personnes qui parlent devant eux, et qui ne prennent pas les précautions nécessaires pour se faire entendre.

En vain répondront on que ces personnes ne savent pas les dispositions qu'elles doivent mettre dans leurs organes, pour rendre sensibles aux sourds et muets les paroles qu'elles prononcent: sans doute elles ne le savent pas, et c'est pour elles une expédition de mystère; mais elles les mettent maladroitement (ces dispositions) dans leurs organes, sans quoi elles ne pourraient parler, et les sourds et muets (instructs) les apercevront toujours, tant qu'on omera, la bonne autant qu'il sera nécessaire, et qu'on parlera lentement en appuyant séparément sur chaque syllabe.

Nous avons cette complaisance pour les étrangers qui apprennent notre langue, et qui commencent à l'entendre et à la parler; et de leur côté ils font la même chose avec nous; que la leur nous est pas familier. Pourquoi n'en usurons-nous pas de même avec les sourds et muets nos frères, nos parents, nos amis, nos commensaux?" (Encyclop. Methodique Arts et Métiers, tom. v. p. 311. 4to. Paris, 1788.)

The last department of the education of the Deaf and Dumb which we proposed to consider, the Explanation of the meaning of words, is both the most interesting to the teacher, and the most agreeable to the pupil.

The method of procedure in this department, which has been practised by Dr Watson, accords, with a very few exceptions, so completely with that, which, after considerable reflection on this subject, we had ourselves set down as the best, that there is little left for us to do, than to state this method, as nearly in that excellent author's words as possible; and to recommend its adoption to all those who would attempt the instruction of the Deaf and Dumb.

In commencing the Explanation of the meaning of words, those terms ought, of course, to be selected at first, which are easiest to be understood. Now, of all the words of a language, the names of the objects that surround us admit of the most direct application, and they most naturally present themselves to begin with. The teacher, therefore, shews a word, by which some familiar object is called; as body, head, face, &c. and the scholar is made to copy it, on his slate, and is taught

Dumb and Deaf.
DUMB AND DEAF.

Familiar objects chosen first.

to pronounce it; he is then shown the object named, and made to point to it, while he pronounces the name; till he remembers the connection between the name and the thing sufficiently, to point out the object when shown the name, or to pronounce and write the name when shown the object. From the parts of the body, we proceed to the covering of it, and learn the names of the articles of dress, in the same manner. We then learn the names of the next most familiar objects; such as articles of furniture, chair, table, &c., always taking care to make perfect as we go on, and frequently going over all we have learnt, till every word becomes familiar in its articulation; orthography, and meaning.

Hitherto all is very easy. The objects, of which we have been learning the names, are within our reach, and about us in our apartment. But we are not always so confined; and we can hardly take a step beyond the threshold of our room, till we meet with something that we know very well by sight, but cannot name. We cannot remove it to our apartment to learn its name there; nor can we very conveniently carry our writing tablets with us, on all occasions.

Here another art, that speaks to the eye, comes to our aid: and the tool of the engraver, by furnishing us, in small compass, with the lines that bound the visual appearances of objects, in perspective order, enables us to keep their resemblances at hand; association recalling those properties which manifest themselves to our other senses.

With this view, Dr. Watson has had executed, for the use of his pupils, a series of engravings, representing, with all the requisite accuracy, upwards of 600 different objects. These are all comprehended in 80 octavo pages, and annexed to his work, which we have already so often quoted. The selection has been made with very great judgment, and cannot fail to be of the utmost use in the education of the Deaf and Dumb.

These engravings are accompanied with a printed vocabulary, consisting of the names of all the objects which the engravings represent, and also of all those words which are explained in the earlier lessons, before the engravings are had recourse to. This vocabulary is arranged in such a manner as to serve another very important purpose, namely, the explanation of a considerable number of general or generic terms. It is classified or divided into sections; at the top of each section is written, in larger characters, a general term; and under this are placed the names of various objects, to which this term is applicable: Thus,

**FISH.**

- Salmon.
- Cod.
- Flounder.
- Sprat.

**FLOWER.**

- Rose.
- Pink.
- Carnation.

**METAL.**

- Gold.
- Silver.
- Copper.

According to this simple and most obvious method, may all **general terms** be explained. We recommend, however, to Dr. Watson, that he should revise his vocabulary for this purpose. It seems to us susceptible of considerable improvement. The generic names are not philosophically chosen, and the illustrations of them are often not strictly accurate.

After having made the pupil familiar with this ex-

**Explanation of General Terms.**

**Explanatory catalogue of particular and general words,** we advise, &c., being disposed to deviate but a little from the plan recommended by this author, and to explain next to the scholar as many of those words which grammarians call **adjectives,** as can conveniently be illustrated by example: And when he has been sufficiently exercised in these, it seems to us, that we ought then to proceed to instruct him gradually in all the remaining kinds of words together; in verbs, and **adverbs,** and **prepositions,** &c., all in connection. For this purpose, we ought to begin with the illustration of short and simple sentences, and proceed by degrees to such as are longer and more complicated. Considerable assistance, we believe, may be derived at the commencement from the engravings by Dr. Watson already referred to; for many of these do not merely represent single and insulated objects, but objects in various relations to other objects, sometimes acting, sometimes acted upon; consequently, they are applicable to a variety of illustrations. All the Plates, from Plate 4. to Plate 23. inclusive, of his work, seem very well adapted to this end. We know not whether the intelligent author has ever applied them in this manner.

But in the more advanced stages, it will be found, that our illustrations must be derived entirely either from actual examples, or from the language of natural signs. Dr. Watson strongly inculcates the propriety of the teacher's learning this natural language from the Deaf and Dumb themselves; and the application which he afterwards directs should be made of it to the purposes of their own instruction, seems to us exceedingly judicious. "Every one," says he, "who would undertake the arduous task of successfully teaching the Deaf and Dumb, should closely turn his attention to the study of that language termed *natural.’" It consists of gesture and feature; in order to enable him to comprehend, as far as possible, the signs of his scholars. Of how much importance it is to a teacher of the Deaf and Dumb to understand their signs, will readily be apprehended, if any one will attempt either to teach or to learn a language, without having another, common to master and scholar. As it, for instance, an Englishman, understanding no language but his own, should attempt to teach it to a German, or rice verb. But never let any thing so chimical be thought of, as an attempt to turn master to the Deaf and Dumb, in the art of signing. Whatever others may say, I own, I have always found it best to become, in some measure, a learner, instead of teacher, of this mode of expression."—"How much more serviceable and useless," he afterwards remarks, "having just supposed a European endeavouring to new-model the scanty vocabulary of a South Sea islander)—"how much more serviceable and useless, is an attempt to methodize signs for the instruction of the Deaf and Dumb! Would it not be a more natural and rational mode of procedure for the teacher to begin, by watching the objects and occasions to which his scholar applies the words of his barbarous speech; that by knowing these he might gradually substitute the words of the language to be taught, using the **former** only as an introduction to the latter?
In the illustration of all those terms which express the various forms of human action, it is obvious, that the greatest advantage might be derived, from the aid of some intelligent assistant not affected with Deafness. If we may judge from the silence of those who have written on the education of the Deaf and Dumb, as to this important help, it does not seem to have been sufficiently employed.

In all that remains, we are inclined to follow Dr Watson implicitly. We perfectly agree with him, that it is altogether injudicious to load the memory of the pupil, at the outset, with those vague and subtle distinctions among words, with which grammarians occupy themselves so much and so unprofitably, and about which the pupils are still so much at variance with each other. It is quite enough, in the first instance, that they are taught, by examples continually diversified and repeated, to use words accurately, and as others use them. The metaphysics of grammar is a fitter study for riper years.

If we be correct in this opinion, it may be doubtful whether the education of those who are not Deaf, might not borrow some improvements from the mode of instructing those who are;—whether the young scholar's earlier years might not be more usefully employed in acquiring, by varied reading, writing, and conversation, greater copiousness, precision, and ease of expression, than in parsing nouns, with out the slightest regard to their spirit or meaning;—whether a few of those precious hours, which are sometimes wasted over the unprofitable pages of some modern Hermes, had not better be devoted to the nobler task of seeking out the strength of our language, and the best array of thought, in the pages of Shakespeare, and Milton, and Addison, and Hume.

After the pupil has proceeded thus far, Dr Watson recommends that he should go over his vocabulary again, with a view to learn the mode of defining words, that is of telling the meaning of one word by another, or by others. He prescribes this employment, not because he thinks he will better understand the words in his vocabulary, by being taught to define them, but because it affords an opportunity of enlarging it, by the introduction of synonymous words, and words that are derived in some way from those we are defining.

The scholar is now sufficiently far advanced to endeavour to acquire both amusement and instruction by reading; and having arrived at this point, Dr Watson imposes on him a new and most important task. To discover the progress he is making, and to assist him in the composition of sentences, he is required every day to furnish a certain number of lines, according to his capacity, from his own ideas. He is at liberty to choose his subject. He may relate what he has seen in his walk, or in his play-ground; he may unfold the stores of his memory, relative to more distant places and periods; he may ask questions, &c. His rude essays at expression are often curious, and require some skill in the language of pantomime to discover their meaning by his own explanations. This attained, it is put into correct, but easy language; he commits it to his memory thus corrected, and goes to work again, at his leisure hour in the evening, for next day, generally profiting considerably by the alterations it was necessary to make in his preceding essay.

This is an exercise which has been prescribed with the utmost success to the pupils of the Institution for the Deaf and Dumb in Edinburgh, by their teacher, Mr Kinimburch. He directs his scholars to address him in the form of letter; and in reading a considerable collection of these juvenile epistles with which Mr Kinimburch has favoured us, we own that we have often been exceedingly delighted with the simplicity and minuteness of the narrative.

Mr Kinimburch, with the same liberality with which he has permitted us to be spectators of his lessons at the Institution, has enabled us to present our readers with the following specimens.

The first is a letter from Charles Mackechnie, a lad of sixteen, who is in the third year of his education, and who can speak tolerably well. It describes a visit to the college court-yard, where a live Polar bear is at present kept, and to the Museum of Natural History.

"Dear Sir,

Edinburgh, March 1814.

Percival Clennell's father, and his brother, and gentleman, came to your house to the parlour, and he spoke to you. When (upon which) you told us, 'Come to me, you will change your coat,' and I went to the closet and changed my coat, and I went down stairs. And we went to the college; and his father met his mother in North Bridge, and we went to the college. And a gentleman went to the house, and took a key out, and came to us. And we went to the door, and he opened the door, and I wondered at a bear. And I saw a fence at the bear, and a lad took a pole, and he held it to the bear, and it roared. And he gave his father a pole, and he took and held it through the fence to take out flesh and bone, and it caught it, and it roared. And Percival Clennell and his brother were afraid of bear in the den, when we went from it to the door, and shut the door. And we went to a house, and man opened the door, and we went to the beasts and birds in the room.

And I saw an elephant's head by the bone, and young lion, and a little ostrich with a big egg, and cassowary, and serpents, and black monkey, and a deer had a long horn, and unicorn has a very long horn, and ducks, and shells, and marbles, and pebbles; and wild shark, and humming birds, and many clothes and shoes for Indian in cup-board hanging on the partition; and his father spelt tow the names of beast and birds.

I am, Sir, your affectionate pupil."

The next is by Joseph Turner, a lad of fifteen, who is also in the third year of his education, and speaks pretty well. It is entitled, a Visit to the Court of Session.

"Edinburgh, 11th Feb. 1814.

I, John Wilkie, and Charles Mackechnie, went to the Court of Session, and we saw a number of gentle men and advocates walking in the Court of Session. And a judge was sitting on a soft chair near the wall. He had a red gown on him, and a powdered wig on his head, and a large white band for a neckcloth on his breast. The advocates were sitting on the form before the judge, and they had black gowns on their bodies, and powdered wigs on their heads. One of the advocates got up from the form, and spoke out to the judge, and he hearkened to him speaking. When he sat down, the judge wrote in a book on the desk. Two advocates got up from the form, and one did not speak out; but the other advocate spoke out to the judge, and he lis-
DUMB AND DEAF.

Deaf.

Dumb and
Deaf.

It was a keeper of bees. My mother told me that I was a good boy to watch the bees flying round the bees- hives in the garden, in the summer or autumn of year 1808 and 1809. It was pleasant; for bees flew round the hives. She told me, that 'you must watch the bees flying round them, if they fly away in the air from the bees-hive.' When (upon which) I ran to my mother's house, and told her that the bees flew away in the air; and then we went to her garden, to see the bees flying in the air. I threw at the bees flying with clay, and my mother beat the iron pan with one iron stick; for the bees sat on the trees in my father's field, and they did not fly. She told me to go and bring another bee-hive, and a table. I went away to the house, and I took them to the field, and I gave them to her. And she put the bee-hive on the tree or the bush near the bees; and I saw she covered her face with a white veil, and she shaded them into the bee-hive from the bush with her right hand. In the evening, I and my father went to his field, and took the bee-hive to his garden, and put it on the broad stone; and we went into his house and rested ourselves.

Yours, &c."

These specimens have been copied literally from the manuscripts of the pupils, and have not undergone the slightest correction from the master. The general turn of the expression in some parts, but particularly in the last specimen, seems to us to bear a striking resemblance to the language of scripture; and yet we are assured, that all these compositions were written before either of the boys had begun to read from books of any sort.

In concluding the consideration of this department, we have only further to remark, that it is quite unnecessary to delay beginning the explanation of words, until a certain progress has been made in Writing, and Dactylogy, and Speech. It might even be entered on, before any of these departments are commenced. The connection betwixt objects and the written characters which represent them, can be established equally well, whether the pupil to whose organs of vision they are addressed, is or is not, able to speak or to write them. The explanation of words, therefore, ought to be begun as soon perhaps as the scholar enters on his education, although but a very small portion of his time can, at this early stage, be devoted to that object.

We have now gone through, with all the minutenes that appeared requisite to ourselves, and per-

haps with more than may have seemed necessary to some of our readers, the different departments of the education of the Deaf and Dumb. We shall be happy if our remarks are found calculated to afford the slightest assistance to any humane individual, who may have resolved to attempt the instruction of any Deaf and Dumb relation or friend, in the privacy and retirement of his own home. But we much fear that private tuition, in the case of the Deaf and Dumb, as well as in that of other children, can seldom be conducted with so much judgment as to afford advantages to the pupil, equal to the method of public instruction. We should wish, therefore, to regard all the early domestic lessons, which the natural affection of a parent may lead him to bestow on his Deaf and Dumb child, in the light merely of preparation for his introduction into some public school.

There is much reason to regret, that the public institutions for this purpose in Great Britain are so few in number. We are acquainted only with two that have yet acquired any reputation, one in London, and the other in Edinburgh.

The former is entitled, the "Asylum for educating the Deaf and Dumb Children of the Poor," and was instituted in 1792. This asylum contains at the present time, if we are not misinformed, about 100 pupils; and these are fortunate enough to have for their instructor, the very judicious person whom we have had occasion so often to quote, Dr Joseph Watson. It does not, however, admit any children on the charitable foundation until they are nine years old. "The reason for fixing upon this age," says Dr Watson, "was not any idea that it was the earliest at which regular education could be advantageously begun; but five years being deemed, generally speaking, sufficient to accomplish that course of instruction thought most essential to children, destined to earn their bread by the labour of their hands, and fourteen being the earliest age at which they could be apprenticed, it was judged best, for the economical purposes of the institution, not to receive them before the age of nine years."

That he may not be misapprehended, Dr Watson afterwards states precisely what he understands by an education most essential to deaf children of the class mentioned. "I deem it essential," says he, "that they should have such a knowledge of language, as to enable them to express their ideas on common occasions; to understand the commands or directions it may be necessary to give them in ordinary cases, &c.; to read with intelligence the precepts, the examples, and the promises, which are contained in the scriptures, particularly the New Testament; that they should write a good hand, spell correctly the words they use, and understand the principal rules of arithmetic. When I say that these acquisitions may be attained in five years, I mean to state that as the shortest time, even where the capacity of the learner is good."

The "Edinburgh Institution for the Education of Edinburgh the Deaf and Dumb Children of the Poor," was established only in 1810. Its objects are precisely the same as those of the London Asylum. It does not admit children before eight, nor after fourteen years of age. It

* A marble statue of the Lord President Forbes.
† Our readers will recollect that this practice is at least as old as Virgil:
    "Hac tu juva adspicer, amicus,
    Fut temetis scilicet, et certanea ignobilem gens.
    Tumnitusque cie, et Matris quae symbala circum."

    GEOR. LIB. IV. V. 63.
already contains 55 pupils, and yet we are persuaded that its advantages only require to be more generally known in this part of the island, to secure to it still more of the public favour than it has already enjoyed. We can speak from our own observation, as to the justice done this institution by the teacher Mr Kinniburgh, who is a person in every respect well qualified for the important and laborious duties of his situation.

We shall conclude this article with a few historical remarks.

If the authorities to whom we have found reference, relative to this point, be correct, a Spanish Benedictine monk, of the convent of Sahagun in Spain, named Pedro de Ponce, who died in 1534, is the first person who is recorded to have instructed the Deaf and Dumb, and taught them to speak. Ambrosio Morales, the contemporary and friend of this Pedro de Ponce, in a work on the Antiquities of Spain, which seems to have been written about 1583, speaks of him thus: "Pedro de Ponce has taught the Deaf and Dumb to speak with singular perfection. He is the inventor of that art. He has already taught, in this manner, two brothers and a sister of the Constable; and is at present occupied in instructing a son of the Governor of Aragon, who, like the preceding, has been Deaf and Dumb from birth. What is most surprising in this art, is, that his pupils, notwithstanding their deafness, speak, write, and reason very well. I have a paper belonging to one of them; Don Pedro de Velasco, the brother of the Constable, in which he tells me, that it is to Father Ponce he is indebted for being able to speak." (Quoted by Don Emmanuel Nunez de Taboada, in a note to p. xxxviii. of Pref. to Anatomie et Physiologie du Systeme Nerveux en General, par J. J. Gall et G. Spurzheim, vol. 1, 4to, Paris 1810.) Valles, also a contemporary and friend of De Ponce's, in a work entitled, De Sacra Philosophia, published about 1588, has this expression respecting him: "Petrus Pontius, Monachus Sancti Benedicti, amicus meus, qui, res mirabilis! natos surdos docebat loqui." In confirmation of these testimonies, Don Emmanuel Nunez, a Spaniard, mentions that, he has read in the register of deaths of the Benedictine Convent of San Salvador de Ona, where Pedro de Ponce passed the greater part of his life, the following note: "Obiit omnivit in domino, frater Petrus de Ponce, hujus demus benefactor, qui, inter ceteras virtutes, quae in illo maxime fuerunt, in hac praecipe floruit, ac celeberissimo tuto urbe fulitus habitus, sollicitus, Mutus Loqui Docendi. Obit anno 1589 mense Augusto." (Work quoted above, p. xl.) The same person states, too, that other Spanish authors, such as Lopez and Castaniza, some of them contemporaries of De Ponce's, also speak of him in the highest terms, and assure us that he not only taught his pupils to speak, but instructed them in every science which it is possible to teach to those who enjoy all the senses.

In the anonymous translation into English of the Abbé de l'Épée's Method of Educating the Deaf and Dumb, (8vo, London, 1801,) the translator, in a preface, makes the following remark: "Of former instructors, he who seems to have obtained greatest notice was Bonet, a priest, Secretary to the Constable of Castile, whose younger brother had lost the sense of hearing when two years old. The difficulty of procuring instruction for him creating much distress in the family, Bonet, qualified for the province of tuition by expert knowledge and uncommon learning, undertook the care of his education; in which he succeeded beyond every hope. The system which he formed on the occasion was printed at Madrid in 1626, under the title of Reductión de las Letras, y Arte para enseñar a hablar los Mudos, dedicated to Philip III. and accompanied, according to the custom of the age, with encomiums in verse and prose, from poets and philosophers. The author is said to have been afterwards in the service of the Prince of Carignan, and to have continued many years to teach persons to whom the misfortune of Deafness made his lessons needful."

Nunez, however, to whom we have already referred, maintains, that Juan Paulo Bonet must have derived his knowledge and his method regarding this subject, entirely from De Ponce; for Bonet was secretary to the Constable at the very time De Ponce was employed in teaching the Constable's two brothers and sister. (Work quoted above, p. xli.) There is, therefore, some obscurity connected with the history of this work, which it will not now, perhaps, be easy to remove. We have neither seen the Treatise itself, nor any account of its contents; but we presume it has considerable merit, as we observe that it was much consulted by De l'Épée, when he first began to teach his pupils to speak.

The translator of De l'Épée's Method, mentions a Dr Bulwer's treatise as having been published by Dr John Bulwer, an English physician, in 1648, entitled, Philosophus, or the Deaf and Dumb Man's Friend. We have not seen this work either; but we believe we can form some idea of its value, from two other short publications by the same author, which appeared in 1644, the one entitled Chirologia, or the Natural Language of the Hand, and the other, Chironomia, or the Art of Manual Rhetoric; in neither of which are there even absurdi ties sufficient to reward their perusal. We presume it is the same Bulwer who wrote a curious book, entitled, Anthropomorphosis; in which he treats of the various shapes and dresses, which men have assumed in the different ages of the world.

In 1653, a work of great labour appeared by Dr Wallis's Writings and Prac- tices, entitled Grammatica Linguæ Anglicæ; and to this was prefixed, by the same author, a treatise of considerable acuteness and originality, De Logueta, sive de Sonorum omnium loquetarium formatione. In consequence of these investigations, his attention seems to have been directed to the subject of the education of the Deaf and Dumb. A very interesting letter of his to Mr Boyle, dated from Oxford, March 1692, is inserted in the Philosophical Transactions for July 1707; wherein he informs Mr Boyle of his having just entered on the task of endeavouring to teach a person to speak and to understand a language, who had lost his hearing, and consequently his speech, when about five years old. He states the considerations which induced him to attempt this work, and the wish he has to conduct it; and nothing can be more sound or judicious than all his remarks on this subject. "The task itself," says he, "consists of two very different parts; each of which doth render the other more difficult; for, beside that which appears upon the first view, to teach a person who cannot hear, to pronounce the sound of words, there is that other, of teaching him to understand a language, and know the signification of those words, whether spoken or written, whereby he may both express his own sense, and understand the thoughts of others: without which latter, that former were only to speak like a parrot, or to write like a scribener, who, understanding no language but English, transcribes a piece of Latin, Welsh, or...
At the conclusion of the letter, he mentions the progress he had already made, which he pronounces to have exceeded his expectations. His pupil had been with him only about two months; and yet in that short time he had got over the greatest difficulties of both departments: there was hardly any word which (with deliberation) he could not pronounce; and he had already learned the meaning of a considerable part of those English words which are in most frequent use.

About thirty-six years after this, a letter of Dr Wallis's was printed in the Philosophical Transactions, (Phil. Trans. 1698, p. 353.) in reply to one from Mr Thomas Beverly, in which that gentleman had requested his advice, relative to the education of five Deaf and Dumb children. In this letter Dr Wallis mentions, that, four or five-and-thirty years before, he had taught Mr Alexander Popham, who had been born Deaf, to speak distinctly, and to understand a Language so as to express his mind tolerably well by writing, and to understand what was written to him by others Prior to this, too, he states his having taught Mr Daniel Whaley; the same gentleman, we presume, whose education he had just entered upon, when he wrote to Mr Boyle in 1662. "Some other Deaf persons," he also adds, "I have not attempted teaching them to speak; but only so as (in good measure) to understand a language, and to express their mind (tolerably well) in writing. Who have thereby attained a much greater measure of knowledge in many things, than was thought attainable to persons in their circumstances; and become capable (upon further improvement) of such further knowledge as is attainable by reading."

After stating shortly the mode of proceeding in teaching the Deaf to speak, and referring to his Treatise de Loquela, with that view, he observes: "This is, indeed, the shorter work of the two, (however looked upon as the more stupendous.) But this, without the other, would be of little use. For, to pronounce words only, without a parrot, without knowing what they signify, would do us but little service. The other part of the work (to teach a Language) is what you now enquire about." He then goes on to detail the method he had followed in this department with success, and which reflects equal credit on his acuteness and good sense.

In the Philosophical Transactions for January 1668, p. 602, there is an account of a small Tract which was published the preceding year, both in Latin and German, by F. M. B. V. Helmont, entitled Alphabetum Naturae. In the first dialogue of the first part, the author is said to treat "of the motions and configurations of the mouth of man; and how a man born Deaf; and consequently Dumb, may come to understand, both them, and by them, the mind of him that forms them; where it is observed, that a man born Deaf is not altogether destitute of all motion of his tongue, and that he may be taught to understand others by the motions of the mouth and tongue, much after the manner as others are taught to read. To which is annexed, a method suitable to that principle, of teaching Deaf and Dumb men to speak; together with an example of a musician, who being altogether Deaf, and weak-sighted withal, was, by the author, brought so far in the space of three weeks, that he was able to answer to all that was spoken to him, provided it were done slowly, and with a well opened mouth; who also afterwards by himself, as soon as he had by this very way learned to know the letters, and to read, did, by confronting only the German and Hebrew Bibles, learn in a short time the Hebrew tongue so well, that now he understands the whole Hebrew Bible."

The subjects of the remaining parts of this work, all relate to Speech or Language; but they seem to be treated in a very whimsical manner.

In 1669, Dr Holder published his Elements of Speech, with an Appendix concerning persons Deaf and Dumb. The appendix contains an account of the method he employed in the education of a Deaf and Dumb person, who was recommended to his care in 1659, and whom he taught successfully to speak. The whole work is rather tedious and obscure.

The translator of De L'Epée's Method, (Pref. p. vii.) refers to a work printed in 1670, entitled A Treatise concerning those that are Born Deaf and Dumb; and bearing the name of George Sibstoffe, as its author. It is said to treat of the tuition of the Deaf and Dumb, rather in a loose and general manner, as a subject of speculative enquiry; but we have never seen it.

The next work, in point of date, relative to this subject, is a small treatise by George Dalgarne, published at Oxford in 1680, under the following title: Dulas-calopochus, or the Deaf and Dumb Man's Tutor, to which is added, a Discourse of the nature and number of Double Consonants: Both which Tracts being the first (for what the Author knows) that have been published upon either of the Subjects.

This treatise is purely speculative. The author does not profess to have actually taught the Deaf and Dumb; he only points out their capability of being instructed, and lays down the general principles according to which he conceives that their Education ought to be conducted. It is obvious, however, not only from the title-page, but also from the whole tenor of his treatise, that he was altogether ignorant of the successful labours of Wallis, and Holder, and the other authors, to whom he has referred, as preceding him in this department; a circumstance for which it is not easy to account, when we consider that he had lived at Oxford for upwards of twenty years prior to the publication of his book.

The only media he conceives, by which instruction can be effectually conveyed to the Deaf and Dumb, or by which they can be enabled to communicate their thoughts to others, are Writing and Manual Speech. He has no doubt that a Deaf Man may be taught to speak vocally; but he seems to think that this sort of speech will always be so imperfect in him, that it is not worth his acquiring. As to such a person's being able, by the eye, to understand the speech of others, he endeavours to prove that that is impossible, by an argument à posteriori, as he calls it, delivered in the regular form of Syllogism.

In consequence of these false views, his attention seems to have been chiefly directed to the improvement of the department of Dactylogy; and after much search and many changes, he fixes on a Finger-Alphabet performed with one hand, which he regards as a very important discovery, and which he describes minutely in his eighth Chapter.

The parts of his treatise, however, which appear to us to possess most merit, are those he entitles the Deaf Man's Dictionary, and the Grammar for Deaf Persons. The general principles according to which he proposes, in these, that the Deaf and Dumb should be instructed in the Meaning of Words, are quite correct; and accord completely with those which Wallis
had laid down in his letter to Boyle, and by which he had actually regulated his practice nearly twenty years before. His method, however, when considered in detail, is inferior to that of Wallis, both in arrangement and perspicuity.

The treatise, taken as a whole, is spirited and amusing; and is, obviously, the production of an original mind.

About the year 1690, a Swiss physician, named John Conrad Amman, was requested to undertake the education of a young girl at Haerlem, who had been born Deaf and Dumb. He succeeded so well in this task, that, in two months, she could not only read distinctly, but could write down whatever was spoken to her; and at last could support a conversation on any subject, and reply with promptness to those who interrogated her; hearing, as it were, by the eyes.

He published an account of the method he employed on this occasion, in 1692, entitled, Surdes Logues. But after having occupied himself occasionally, as it would seem, in this species of education, for several years, during his residence as a physician at Amsterdam, he published this essay under an enlarged form in 1700, entitling it Dissertatio de Loguca. In this Dissertation he treats, not only of the means by which the Deaf and Dumb may be taught to speak, but of Voice and Speech in general, and of the nature and treatment of certain impediments or imperfections of Speech. The treatise is inferior, we think, in all its branches, to the writings of Wallis on the same subjects, but superior to the work of Holder. The author does not seem to have been aware when he composed it, that so much had been written before him relative to the Education of the Deaf and Dumb. He only became acquainted with what Wallis had done in this department, when his Dissertation was printing.

After this period, the number of teachers of the Deaf and Dumb seems to have increased very rapidly on the continent.

In 1749, the Royal Academy of Sciences at Paris, report very favourably, of the exertions of a M. Pereire, who seems to have been employed for some time previously, in educating the Deaf and Dumb in that city.

They state, that M. Pereire had presented to the Academy, two young persons born Deaf and Dumb, whom he had instructed to understand whatever was addressed to them, either in writing or by signs, and to reply either in writing, or vivâ voce; that they read and pronounced all sorts of expressions in French; that they were acquainted with Grammar and Arithmetic; and knew a little of Geography: That Pereire, in addressing his pupils, employed either Writing, or a Manual Alphabet; but that he hoped to teach them, in time, to comprehend what was said to them, merely by the motions of the lips; that the progress of his pupils shewed the goodness of his Method of Instruction, which, however, he kept a secret; and that the Academy conceived they could not too much encourage M. Pereire to cultivate so useful an art. (See Hist. de l'Acad. Roy. des Sciences, 1749, 8vo. p. 209.)

It does not appear that Pereire ever published a systematic account of his mode of Instruction. But De l'Epee asserts (with what truth we know not) that he had profited by the labours of Wallis, and Bonnet, and Amman. (p. 277, of Work quoted at p. 187.) A well written memoir of his, however, will be found in the 5th volume of the Memoires Présentés à l'Académie Royale, (4to, Paris 1768,) in reply to one inserted in the same volume by M. Ernauld. In this memoir, besides vindicating his claim to the discovery of a very curious fact relative to the Deaf and Dumb, namely, that they may be taught to distinguish sounds to a certain extent, merely by the impressions produced on their skin by the breath of the person speaking, Pereire points out several very important distinctions in the degree of Deafness, with which different Deaf-mutes are affected.

M. Ernauld, who called forth this Memoir from Pereire, undertook the education of two Deaf-mutes at Bordeaux in 1756, and the following year they appear to have been presented to the Royal Academy of Sciences. But there is every reason to suspect, that he had derived hints of the method he pursued from Pereire, and that he acted unaidingly towards this person. The Memoir, besides some general observations, contains an account of his successful progress with a third pupil.

From the report of the Royal Academy, it would appear that, prior to Pereire's lessons, Emmanuel Ramirés, Pierre de Castro, and Father Vanin, had been employed in teaching the Deaf and Dumb in Paris; and Ernauld mentions, in 1768, that Rosset, Professor of Theology at Lausanne, and Rousset, residing near Nimes, had then devoted themselves to this occupation. None of these individuals, however, seem to have communicated either their methods, or the results of their exertions, to the public.

No person, perhaps, has ever conducted the education of the Deaf and Dumb, in all its branches, with more distinguished success, than Mr Thomas Braidwood. Mr Braidwood was the first person who kept a regular academy, for this purpose, in Great Britain. He entered on the profession, with a single pupil, at Edinburgh, in 1764; but the number of his scholars increased with his reputation, and he continued teaching a large school, for many years, in this city, and afterwards at Hackney, near London, until his death in 1806. Innumerable testimonies might be produced as to the great proficiency of his scholars; but we shall content ourselves with selecting one or two sentences from Dr Johnson on this subject, who visited Mr Braidwood's academy, while in Edinburgh, on his return from the Western Isles, in 1773.

"There is one subject of philosophical curiosity," says he, "to be found in Edinburgh, which no other city has to show; a college of the Deaf and Dumb, who are taught to speak, to read, to write, and to practise arithmetic, by a gentleman whose name is Braidwood. The number which attends him, is, I think, about twelve, which he brings together into a little school, and instructs according to their several degrees of proficiency."

"—This school I visited, and found some of the scholars waiting for their master, whom they are said to receive at his entrance with smiling countenances and sparkling eyes, delighted with the hope of new ideas."

"—The improvement of Mr Braidwood's pupils is wonderful. They not only speak, write, and understand what is written, but if he that speaks looks towards them, and modifies his organs by distinct and full utterance, they know so well what is spoken, that it is an expression scarcely figurative to say they hear with the eye."

He afterwards adds, in his characteristic manner: "It was pleasing to see one of the most desperate of human calamities capable of so much help; whatever enlarges hope, will exalt courage; after having seen the
Dumb and Deaf.

Dr Watson.

Deaf taught arithmetic, who would be afraid to cultivate the Hebrides?" (Journey to the Western Isles.)

It is said that Mr Braidwood was restrained from laying his system before the public, solely by a persuasion that he could not explain it in words with sufficient precision to enable any one to act upon it. But we fortunately possess the means of appreciating its merits fully, in the work of his relation and able assistant Dr Watson; who, it is generally understood, teaches according to the principles of his master. That work, to which we have already referred so frequently, is, without any exception, the best that has yet appeared relative to the education of the Deaf and Dumb. How far Mr Braidwood was acquainted with the writings of Wallis we know not; but his general views are the same. Dr Watson seems to have methodised and improved the systems of both.

De L'Epee.

All this had been done and written, before the name of De L'Epee was known. But chance now directed the attention of this reverend person to the education of the Deaf and Dumb; and he had soon the good fortune, not only to acquire a much more general reputation throughout Europe, than ever had been enjoyed by his predecessors or cotemporaries; but even to be looked on with admiration by many, as the first philosopher who had discovered the possibility of illuminating the minds of this unfortunate class of persons.

The Abbé happening to go into the house of a lady in Paris, who had two daughters that were born Deaf and Dumb, found her disconsolate for the death of their preceptor Father Vanin. He was touched with pity for their condition, and went home reflecting how he could best supply the place of their teacher. Soon after, he returned; put some of his reflections to the test of experiment; was satisfied; and resolved to become their preceptor himself. Thus began his philanthropical exertions as an instructor of the Deaf and Dumb; and this commenced his fame.

The English translator of his Method informs us, (Pref. p. viii.) that the Abbé instituted a seminary, in which he received as many of the Deaf and Dumb, as he could superintend, and formed preceptors to teach those in distant parts. "The number of his scholars," says he, "grew to upwards of sixty; and, as the fame of his operations extended, persons from Germany, from Switzerland, from Spain, and from Holland, came to Paris to be initiated in the method he practised, and transfer it to their several countries."

"The expenses," this author observes afterwards, "attending the seminary which he established, were wholly defrayed by himself. He inherited an income, as M. de Bouilli informs us, amounting to about 14,000 livres, (nearly L. 600 sterling) of which he allowed 8000 for his own person, and considered the residue as the patrimony of the Deaf and Dumb, to whose use it was faithfully applied. So strictly he adhered to this appropriation, that in the rigorous winter of 1788, when in his 65th year, and suffering under the infirmities of age, he denied himself fuel rather than intrust upon the fund he had destined them. His housekeeper having observed his rigid restriction, and, doubtless, imputing it to its real motive, led into his apartment forty of his pupils, who besought him, with tears, to preserve himself for their sakes. Having been thus prevailed on to exceed his ordinary expenditure about 300 livres, he would afterwards say, in playing with his scholars, "I have wronged my children out of a hundred crowns."

In 1776, he published a work in French, entitled Institution of the Deaf and Dumb by the way of Methodical Signs; and, in 1784, a new edition of this, much altered, appeared under the title of, La véritable manièr e d'instruire les sourds et muets, confirmée par une longue expérience. It is this last work which he introduced into the Encyclopédie Méthodique, under the article Muets et Sourds, (part referred to at p. 187,) and which was translated into English, anonymously, at London, in 1801.

He continued to teach at Paris, with unremittent perseverance, until 1790, when he died, aged 67.

After the great and almost universal celebrity which the Abbé seems to have acquired, we shall hardly be listened to when we affirm, that the system which he taught was utterly useless. Yet that this was the case, is but too obvious from the works which he himself has published,—from the criticisms made on his method in the work even of his pupil and successor Sicard,—and from his own confidential letters respecting it, which Sicard has presented, along with these criticisms, to the public.

When he first began his career as an instructor of the Deaf and Dumb, he seems to have been entirely ignorant that Pereire was then teaching, and had taught, for several years at Paris; or that this species of education had ever been the subject, either of speculation or practice, at any former time, or in any other country; and he confesses that it never occurred to him to be practicable to teach his pupils to speak. But the works of Bonnet and Amman soon became known to him; and, guided by their direction, he seems to have succeeded in bestowing the gift of Speech on several of his scholars. Latterly, however, he appears to have neglected this branch very much; whether from a mistaken idea of its inutility, or really (as he professes) from his inability to undergo the labour of teaching a number of pupils at once, is very doubtful. In the part of his book which relates to this subject, he pretends to no more, than to have added a few reflections of his own, to what he had found in Bonnet and Amman.

But the peculiarity of his method of education, and the object to which every other seems to have been sacrificed, was his system of "Methodical Signs." This was an extremely complicated Language of the Hand, representing, not single letters as in the common Manual Alphabet, but whole words; and the sole occupation of the pupil seems to have been, acquiring this language, and converting Methodical Signs into Writing, or Writing into Methodical Signs, according to the dictation of the master.

It is only necessary to reflect, however, that this system of signs was entirely peculiar to De l'Epee, to perceive that it must have been altogether useless to his pupils as soon as they passed from school into society; and that it was an absurd and inexcusable waste of time to teach them a complicated artificial language, which was perfectly unintelligible to the whole of the rest of the world. It is true, indeed, that while the Abbé instructed his scholars in these Methodical Signs, he professes also to have taught them the meaning of the words which they were intended to represent. But whatever may have been his wishes or his professions on this subject, the fact is, that the stock of words which they actually understood, seems to have been exceedingly small. He appears to have established in their minds, merely an association between Manual Signs and Written Characters; neglecting or failing to accomplish a connection of infinitely more importance, that between
Written Characters and Things. They appear not to have been trained to any original exertion of intellect; the composition of a sentence even of moderate length in French, was a task of which they were incapable; in all those public trials before kings, and princes, and philosophers, of which Europe has heard so much, the pupils had question and answer alike dictated to them by their teacher, without their knowing in general the real meaning either of the one or the other; and those parents who fondly flattered themselves, that when their children returned from the instructions of De l'Epée, they would be enabled to enjoy the interchange of ideas with them through the medium of writing, were mortified to find that they knew not how to ask a single question themselves, and that to all those that were addressed to them, they could only answer by a yes or a no.

These imperfections in the Abbé's system do not seem to have entirely escaped the notice of those who visited his public lessons, or the lessons of persons who had been taught under him. His method was introduced by Pereire and Nicolai; and although an attack made on it by Heinich, a teacher of the Deaf and Dumb at Leipsic, called forth a decision of the Academy of the Northumber in favour of the Abbé, yet we do not think that that learned body acquired much reputation by their defence.

Two documents have been preserved by Sicard (who, certainly, has not been over-greatful of the reputation of his master, in presenting them to the public), which show, in a very unequivocal manner, how very limited De l'Epée's notions were as to the extent to which the education of Deaf and Dumb persons might be carried; and clearly develop the real object (we had almost said the whole trick) of that system, according to which so many were taught, and by which so few profited.

Sicard, in conducting the education of a Deaf and Dumb pupil at Bordeaux, had communicated to the Abbé an account of his progress, and of some deviations which he had ventured upon from the Abbé's method. De l'Epée replied in a letter, from which we translate the following extract.

"I applaud sincerely your success, my dear colleague, (I set you the example, I wish no more to be called master), but I fear much that you are becoming the dupe of an ambition to make your pupils metaphysicians. Don't imagine that they will ever be able to express their ideas in writing. Our language is not theirs; theirs is the language of signs. Content yourself that they know how to turn ours into theirs, just as we ourselves translate foreign languages, without knowing or caring how to express ourselves in them. Is it not enough for your glory, to be destined to partake of mine? And what more is necessary to secure this, than that your pupils, like mine, should merely know how to write, to the dictation of signs?"

Another letter, written a few weeks afterwards, is still more explicit. The following is a translation of it.

"What, my dear colleague, your pupils not yet know how to write short sentences, to the dictation of signs! What are you doing? What are you trifling about? You wish absolutely to make writers, when our method is in fact capable only of making copyists. You have assisted at all my public lessons; have you ever seen that the spectators required of my pupils what you expect of yours? If questions have been occasionally proposed to them to answer, these have been short familiar interrogations, which are always the same; and yet you have seen that the greatest persons of the court and the city, and even foreign princes, have asked no more. Take my advice, my dear colleague; renounce your pretensions, which smack a little of the 'Garonne'; and satisfy yourself contentedly with the portion of glory which you see me enjoy. Teach your pupils, without delay, declension and conjugation; teach them the signs of my dictionary of verbs; teach them to construct parts of sentences, according to the table of which you have a copy, without flattering yourself that your scholars will ever express themselves in French, more than I can express myself in Italian, although I can translate that language very well." (p. 484 of Work quoted at p. 183.)

We have done with the Abbé de l'Epée. That he was industrious, and ingenious, and singularly benevolent, is beyond all question; but it seems to us equally clear, that, as a teacher of the Deaf and Dumb, he was greatly inferior to most of his predecessors, in the soundness of his principles and the utility of his practice. We think too, that we are fully justified in adding, that, in order to secure that glory which he loved, he seems occasionally to have indulged in an empiricism which it became him to despise.

There is an essay on the "Method of teaching the Deaf and Dumb to Speak," by Dr William Thornton, in the third volume of the Transactions of the American Philosophical Society (4to, Philad. 1793, p. 310); but it contains nothing that may not be found in the works of preceding authors. The treatise to which it is appended, on the Elements of Written Language, contains observations which have a much better claim to originality.

The latest work on the Deaf and Dumb, is that of the Abbé Sicard. Sicard, after having been for some time the assistant of De l'Epée, first employed himself as a teacher at Bordeaux. But on the death of his master at Paris, he was appointed to fill his place, and he now conducts a very numerous seminary in that city. Although he still continues to trammel his pupils with the system of Methodical Signs, he has so far improved upon the method of his predecessor, that he instructs them fully and correctly in the meaning of words, and teaches them to compose for themselves. Many of them, we have understood, are extremely intelligent; but why he does not teach them Speech, we know not. If, however, the method which he pursues in instructing Massieu at Bordeaux, and the detail of which constitutes his work, be that which he adopts in general towards all his pupils, we must say, that his system is one of the most tedious, intricate, and metaphysical, that it is possible to conceive. They who have profited by the simplicity and good sense of Wallis and Watson, will not be readily prevailed on to wade through many pages of the declamation and useless subtlety of Sicard. (q. s.)

DUMB, DEAF, AND BLIND. For an account of an interesting young lad, born in this unfortunate condition, see MITCHELL.

DUMBARTON, a town of Scotland, situated at the confluence of the rivers Clyde and Leven, and within the parish and county of the same name. Dumbarton (the fort of Britons) was the ancient name of the castle, which has been a place of strength from the earliest times, and was long deemed impregnable. It is a bold and insulated basaltic rock, rising to a great height out of the sands on the north side of the Clyde.
DUMBARTONSHIRE, a county in Scotland, (formerly Lennox,) consists of two parts, separated from one another. The western is the larger, being about 40 miles in length from north-west to south-east, and where the broadest, about 12 in breadth from north-east to south-west. The other division is about 12 miles in length from east to west, and four in breadth. The former is bounded on the north by Perthshire, on the west by Argyllshire and Loch-long, on the south-west by the Clyde, on the south by Lanarkshire, and on the east by Stirlingshire; the latter is encircled by Lanark and Stirlingshires. The county lies between 55° 58' and 56° 23' of north latitude, and between 3° 55' and 4° 53' of west longitude. No accurate surveys have been made of the superficial extent of this county; but from the most plausible computations, it is stated to be about 230 square miles, containing 147,500 English acres, or nearly 116,000 Scotch acres, exclusive of lakes and arms of the sea within its boundaries. This shire takes its name from Dumbarton, the county town.

The county of Dumbarton was formerly a part of the regality of Lennox. Since the abolition of heritable jurisdictions, it forms a sheriffdom by itself, and it sends a member to parliament. This county is divided into 12 parishes. It is within the commissariot of Glasgow; and the civil and ecclesiastical jurisdictions in it are the same as those common to the rest of Scotland.

The county of Dumbarton embraces every variety and every beauty in the scenery of Scotland. Of its charms, in this respect, no adequate description can be given. The most conspicuous object of admiration is Loch-lomond. This fine lake is 30 miles in length, and in some places eight or ten in breadth; its surface is above 20,000 acres in extent, its greatest depth 100 fathoms; the bottom, to the depth of five feet, being composed of fine mud mixed with mica. It contains 30 islands of various dimensions, one of which extends to about 150 acres. These are scattered on the bosom of the lake, some of them scarcely appearing above it, and others swelling to a greater height; some of them tufted with wood, and others more sparingly supplied with foliage. The well-wooded banks, the soft and verdant fields, and the rugged and towering mountains which rise on the northern verge of the lake, produce the most picturesque combination of beauties in landscape on which the imagination can dwell. One of the islands, Inch Murrin, feeds about 300 deer. On the west end of it, the ruins of an old castle, an ancient residence of the Earls of Lennox, stands; and near it the Duke of Montrose, in 1793, built a neat hunting box. A gamekeeper and his family are now the only inhabitants. The north end of the loch is never frozen, but towards the south it has often been; and after great floods it has been known to rise six feet higher than usual. In 1755, when there was an earthquake at Lisbon, Lochlomond was agitated, and rose and fell for some time above and below its ordinary level. Its surface is sometimes ruffled with undulations when there is no wind to produce such an effect.

This county, from the latest and best information, Population, contains about 21,759 souls. In 1756, it was said to contain 13,253; and, when the Statistical Account was published (1790-8), 17,745; being an increase, in 54 years, of 8490. This increase is to be ascribed chiefly to the establishment of numerous manufactories. The number of landed proprietors is 149; the valued rent is L33,382, 7s. 8d. Scots; the real rent, as nearly as can be ascertained, L56,000. No proprietor of land perhaps draws an annual revenue from his property above L3000; and none of them have very large estates. The farmers are, generally speaking, possessed of very moderate skill, and very little capital; and these facts
DUMBARTONSHIRE.

being stated, we need hardly add, that agriculture is not in its most improved state. The lands, however, are let on leases, and improvements are gradually creeping in, although they must struggle at once with the poverty and the prejudices of the inhabitants, in whose character there is nothing very prominent to distinguish them from that of the adjacent counties.

The only river of any consequence which can be said to belong to Dumbartonshire is the Leven. This stream is the outlet of Lochlomond, after leaving which it runs with a rapid current for about five miles through a fine valley, till it joins the Clyde at Dumbarton castle. In spring and autumn there is an imperfect navigation on the Leven for lighters and small craft, which float down the stream, and are towed by horses in an opposite direction. The other rivers are Foon, Luss, Finlay's Douglas, and Falloch, all which are mountain torrents, falling into Lochlomond and Laggie.

In the parishes of Kirktunlloch and Cumbernauld, and also in the eastern part of the larger division of the county, the predominant soil is what in Scotland is generally called till; a shistose clay mixed with a few small stones, impervious to moisture, and generally incumbent on sand-stone. Along the banks of the Clyde, in the parishes of Dumbarton and west Kilpatrick, there are many fields of a rich black loam, of the most fertile quality, though suffering from moisture on account of their being but little elevated above the surface of the river. Some fields of nearly a similar description are to be found on the banks of the Endrick, in the parish of Kilmarrock, and of Kelvin near Kirktunloch. On the river Leven, and to the northwest of that stream, the arable land is, for the most part, of a light gravel, mixed on the seashore with shells and other marine productions, and covered with a thin stratum of vegetable soil. The extent, however, of arable ground of every description is inconsiderable, as by far the greatest part of the county consists of lofty mountains, incapable of any thing like cultivation. In the parish of Arroquhar, which is more than twelve miles in length and four in breadth, and consequently must contain 24,000 acres, there are not 200 arable, or capable of being made so. This parish is indeed singularly mountainous, and rises in some places to the height of no less than 3000 feet above the level of the sea; but the parishes of Rew, Roseneath, and Luss, are also, for the most part, composed of mountains, and have comparatively but a small proportion of arable or low pasture. In Cardross and Bonhill, there is a considerable track of high moor; and that part of the west division of the county which lies to the east of the river Leven, is intersected by a continuation of the lovely ridge, which crosses the island from Forfarshire to the Frith of Clyde.

Oats have been long the grain chiefly cultivated in this county. Barley was some years ago raised to a considerable extent, but the high duty on malt, and the demand for wheat, have induced the farmers to give it up in a great measure, and during that period a great quantity of wheat has been raised. Beans are sown in greater quantities than peas, and their culture is daily becoming more general. Spring tares are the only kind to be seen, and these only on the farms of a few gentlemen. Potatoes are cultivated in the most complete manner, and with great success, and are planted on every variety of soil. Swedish, common white, and yellow turnip, and carrots, are cultivated. Rye grass is universally sown for hay. White clover grows naturally on all the dry land, and red clover is sown down with rye grass, but seldom by itself. Flax is less cultivated than formerly, but a little is raised on almost every farm.

There is little rich land kept exclusively for pasture. On most farms the improved husbandry prevails; and each field in rotation, after having been pastured two or three years, is broken up and returned for tillage.

Cows and oxen are chiefly brought from the west Highland, and milch cows from Ayr and Renfrew; only a small proportion are reared in Dumbartonshire. The number of horses in the county, however, is by no means considerable. The only sheep in Dumbartonshire are of the black-faced or mountain breed, with the exception of a few English of the Leicestershire breed, kept by some gentlemen around their houses.

An abundant and truly valuable source of melioration to this county is found in the sea-weed, which is cast in by the sea, and collected on its shores; but it is reckoned much more valuable, when it can be cut with sickles, at low water, in the spring, when it is in a high state of vegetation, and full of sea salts. It can only be cut once in two years, and so soon as it is cut, it is spread very thin on the ground, and ploughed down immediately before its fertilizing juices are exhausted. Lime is much used, and sometimes shell sand. The soil and grounds are, in many places, well adapted for irrigation.

The wages of a farm-servant in 1811, was estimated at L. 18, L. 22, L. 28, and sometimes L. 30 a year, and a woman for farm-work will get from L. 8. to L. 12. a year, and a day-labourer has 2s. and 2s. 6d. per day.

The average price of beef may be estimated at 61. per pound, mutton 9d. veal, pork, grain, and vegetables, are in proportion still dearer. Salmon 1s. 6d. per pound, and salt herrings sell high, as well as every kind of food, owing to its vicinity to large towns.

Copse woods form a very important article in this county. They cover some thousand acres of soil, which would otherwise be altogether or nearly useless, and yield an income to the proprietors almost equal to what they derive from their best lands. Large tracts of land formerly barren are made to yield a large and useful produce. During the last thirty years large plantations have been formed.

Amongst the various extensive manufactures established in this county, the printing of cottons is the most important. It is carried on by seven different companies; and besides the bleaching of printed goods, there are nine bleachfields for whitening cotton goods; three cotton spinning mills; three paper mills; and at Dalmuir iron work, nails, edge tools, and all sorts of wrought iron goods are manufactured on an extensive scale. A large glass manufactury is carried on in Dumbarton. Alkali is manufactured at Burnfoot of Dalmuir. At Millburn there is a distillery of pyroglucious acid. This liquor is employed in making colours for calico printers, and while this liquor is distilling, a quantity of tar and charcoal is produced; and in the town of Dumbarton there are a few taw works.

The only branches of commerce which deserve to be noticed are the importation of grain, and the exportation of the produce of the salmon and herring fisheries. The former of these has long been the staple trade of the port of Dumbarton.

The total gross produce of the salmon fisheries will probably be rather undervalued if stated at L. 1000 a year, and the gross value of the herrings annually caught, (although there are no regular fisheries,)
DUMBLANE, a town of Scotland, in the county of Perth, is pleasantly situated on the banks of the river Allan. It contains many good houses, but is principally celebrated for its cathedral, which was founded by King David I. in 1142. This venerable edifice stands on an eminence on the eastern bank of the river, and overlooks the town. It is 246 feet long, and 76 broad; the height of the walls is 50 feet, and that of the tower, which is a modern building, 125 feet. The cathedral is unroofed; but the choir is kept in repair as the parish church. There are 32 prebends at the west end of the bishop and dean's seats, made of elegantly carved oak, on the north of the entrance to the cathedral.

The following is an abstract of the population return for the parish in 1811.

SITUATION.

DUMFRIES, formerly Drumfries, the chief town of a county of the same name in the south of Scotland, to which it gives its name, is delightfully situated in the vale of Nith, on the left bank of that beautiful river, and somewhat more than a mile below its confluence with the Cluden. There are no historical documents extant by which we can ascertain at what period this town was founded. From some remains of antiquity, however, particularly from two circular mounds retaining the Saxon appellation of moat, one of which was lately to be traced on the high ground at the north end of the burgh, and the other of which is still visible on an eminence to the south-east, we may conjecture that this was a place of considerable resort before the close of the eighth century. If we are to credit etymologists, who derive Drum-fries from two Gaelic words, Drums-fhreas, a hill covered with brushwood, this place must have received its present name before it could boast of a numerous population. It does not appear that there is anything on record relative to its history previously to the middle of the 15th century, when a convent was erected, for friars of the Franciscan order, on a sloping bank, at no great distance from the first of the moats just mentioned. The situation of this religious house must have been very fine. To the north-west, it commanded the rich dale of the Nith, embracing the neighbouring Abbey of Lincluden, 1 and the more distant castle of Dalwinton, then the chief residence of the Comyns. To the eastward stretches the beautiful range of gently rising hills, on which were erected the strong castle of Tortorward, and Amisfield the seat of the once powerful clan of Charteris. To the south-east, romantically seated in the foreground, at a place still named Castle-dykes, was another fortress belonging to the Comyns, 2 with the placid Nith gliding past, and slowly winding through a fine holm 3 towards the Solway Frith; and in that direction the view is bounded by the distant mountains of Cumberland. Nearly due south, the huge Girfeil 4 is the most prominent object, to the right of which is seen a ridge of more rugged and highly picturesque mountains in Galloway; and to the west, upon an extended plain, terminated by the swelling hills of Irongray, stood Terregles, the residence of the Maxwells, chiefs of Nithsdale. The base of the mountain on which the convent stood is washed on the north and west by the Nith, which here makes a beautiful sweep to the southward.

To facilitate the communication of Dumfries with Galloway, the munificent foundress of this edifice caused a bridge 5 to be built across the river, at the spot most convenient for the inmates of her friary. The narrow street which leads from this bridge to the spot where the convent stood, retains the name of the Friars' Vane.

Dumfries having never made a conspicuous figure in history, its annals can only be traced by incidental and insular notices, a few of which it may be proper to specify. It was in the chapel and cloisters of the convent just named, that the two Comyns were slain 6 by the patriotic King Robert Bruce, 7 who was aided on this occasion by Roger 8 de Kirkpatrick, and James Lindsay.

In 1307, the year after Bruce's coronation, when the "proud usurper" again forced Scotland for a time to bear the English yoke, Edward II., advanced to Dumfries, and there received the reluctant homage of several Scottish noblemen. It is even stated by some historians, that he then held a convention of the estates in that town.

From its vicinity to the borders of the rival kingdom, Dumfries was peculiarly liable to the ravages of invaders. It was burnt by the English before 1448, when the Lord Maxwell gained the battle of Sark; and in 1830, it again fell a prey to the flames kindled by these deadly foes. This latter injury did not pass unpunished. It was amply revenged by the Lord Maxwell of the day, who, in the bold spirit of enterprize peculiar to the times, penetrated into England with a small but chosen body of retainers, and having entered Penrith, took the market-cross, by way of bravado, in his arms, and his troops dispersing through the town, reduced it

---

1 Lincluden was built about 100 years before.
2 It is not known at what time this building was erected. There is an item in the accounts of the Comptroller of the Wardrobe to King Edward I. which marks the partiality of the English monarch to his protege, 3 and seems at the same time to imply, that the country here described had at that time been deficient in one great ornament, wood. We allude to a charge for a palisade granted by Edward for this castle, from the forest of Inglewood in Cumberland.
3 Then called Comyn's Holm, now Kingholm.
4 In a vale at the foot of this conspicuous mansion, rose the beautiful abbey of Sweet-heart, which was founded by the same pious individual as the convent at Dumfries; viz. Dervegled, or Dervegills, daughter to Allan, Lord of Galloway, and the mother of John Baliol, King of Scotland.
5 This structure is said by some to have consisted originally of thirteen arches, by others of ten; but the number is now reduced to eight, which are still in tolerable preservation, and in consequence of the river having shifted its channel from the right bank, are quite sufficient. This bridge is used only by foot passengers.
6 In consequence of a deed so sacrilegious as the shedding of blood before the very altar, the friary is said to have been interdicted, or at least deserted. Certain it is, that the people began, soon after this period, to resort in greater numbers to St Michael's chapel, at the other end of the town, where St Michael's church now stands.
7 He was son to the cousin-german of the foundress of this edifice.
8 Mr Hume erroneously names this patriot Thomas. The family records bear that he was called Roger.
in a few hours to ashes. About this period, the Maxwells, having increased in power, erected a magnificent castle at Dumfries, out of the ruins, and almost occupying the site of the friary.

We hear little more of Dumfries till the year 1563, at which date Queen Mary and her privy council were there, ratifying a convention of peace with England. Two years after this, her disaffected subjects, having assembles a force in the neighbourhood, under the Earls of Argyile, Murray, and Rothes, Mary advanced upon the town with an army of 18,000 men. At her approach, these obnoxious nobles fled into England; and Maxwell of Terregles, who, on her former visit, had entertained the queen at his house with much hospitality, having now incurred the royal displeasure, was glad to make his peace by surrendering his castle of Dumfries into the hands of his sovereign. The government of this fortress, however, was not withdrawn from the family; for in 1567, we find it vested in the same Maxwell, who, the year before, had by marriage acquired the title of Lord Herries, and was then devoted to the interests of the queen. It was probably in consequence of the decided attachment shewn by so powerful a nobleman to the cause of his mistress, that the populace of Dumfries tore from the market-cross the herald who attempted to proclaim the Lord Murray regent.

In 1570, the castle was taken and sacked by the English under the Earl of Sussex and Lord Sceope, who at the same time did not fail to ravage the town also.

In 1617, after having been many years resident in England, James VI. being seized, as he told his privy council, "with a longing to see the place of his breeding, a salmon in his instinct," set out on a tour through the northern division of his empire, and in his return passed through Dumfries, a place which he had not seen for 29 years before. Here he experienced a reception at once dutiful and affectionate; and it is believed that, on this occasion, as a reward for their loyalty, and an encouragement to martial exercises, he presented to the incorporated trades of the burgh a small silver tube in the form of a gun-barrel, as an honorary prize, to be awarded from time to time to the best marksman amongst their members.

There does not appear to be any thing in the annals of the town worthy of record from this date till 1706, in which year the inhabitants manifested their keen participation in the jealousy excited among their countrymen, by the incorporation of the kingdom with England. On the 20th Nov. a tumultuous meeting assembled at the cross, and there indignantly committed to the flames the articles of Union, with the names of the commissioners. When the rebellion broke out, however, in 1715, the Dumfriessians retrieved their character, and evinced the most ardent zeal in the cause of the reigning family. Hearing that the insurgents intended to march upon the town, they constructed a rampart 1 from the margin of the river, near the most above the town, to St Michael’s church-yard, and from thence to the river again below the town, which was thus completely insulated, being embraced betwixt the extreme points by the natural curve of the Nith. These preparations for resistance proved effectual. The enemy, seeing the determined loyalty of the inhabitants, did not venture forward to the assault, but judged it most prudent to alter the direction of their march. In the rebellion of 1745, however, the town was found in a defenceless state, and was entered without resistance by the insurgent army under Charles, who remained from Saturday evening till Monday morning, and laid the citizens under contribution.

Dumfries has one vote out of five for a member of Parliament. The other burghs grouped with it are Aman, Lochmaben, Sanquhar, and Kirkcudbright. Its municipal government is vested in a town council, aided, in terms of an act of Parliament passed in 1811, by 12 commissioners of police. The council consists of a provost, three bailies, a dean of guild, a treasurers, 12 merchant councillors, and seven deacons of incorporations, in all 25 members. These choose their successors in office, except the deacons, who are annually elected by their respective trades. As nearly as can be ascertained, there are 30 hammermen, 77 squreman, 60 weavers, 40 tailors, 132 shoemakers, 8 skinners, and 17 flesher, in all 464 freemen.

The council chamber being an inelegant and inconvenient apartment, the magistrates, on solemn occasions, assemble in the county court-house, in which they have a share. Here, too, the circuit Court of Justiciary for Dumfries-shire and Kirkcudbright, the sheriff’s court, and the quarter sessions, are held, as well as all county-meetings. The place, however, though new, is ill suited to these purposes, and a large building on the opposite side of the street, originally a place of worship, is about to be prepared for the more convenient accommodation of these courts, after the plan of an eminent architect.

Behind this court house, in a low damp yard, surrounded by a high wall, stands the new county jail. The debtors have the liberty of exercising themselves in this inclosure, the situation of which has certainly not been selected by a medical man. The building is, withal, inconvenient, and much too small for the accommodation of the prisoners; but the removal of the courts, according to the projected improvement, will enable the county to provide more effectually for their health and comfort. Till 1807, the jail was in the centre of the town. The trades’ hall, a chaste and handsome structure, was built in 1804. Besides the apartment peculiarly appropriated to the incorporations, there is one allotted to the meetings of friendly societies for the aid of sick members, or widows and orphans. The trades, as a body, possess a fund of this nature, and each incorporation separately has one of its own; but besides these, there are many private institutions of the same kind in the town.

1 Castle Street in the modern town, passes through what formerly constituted the grounds attached to this edifice, and the place is still correctly named the Castle Gardens.

2 This royal gift the trades preserve with pious care, and on the day appointed for the contest, (a day which recur every five or six years, or oftener if the parties concerned be so inclined,) the silver gun is conveyed in grand procession to a field, where, after having been shot for, it is suspended by a ribbon to the hat of the victor, who enters the town with it triumphantly displayed, and remains its nominal possessor till the next festival of the kind. On these occasions, there is a mazy jousting of the tradesmen, who are all obliged, under a penalty, to answer to their names, and to appear armed with muskets. See Mr Mayne’s poem, entitled the Silurian.

3 A little mount at the east side of the town, near the junction of the roads leading from Annan and Lochmaben, well known by the name of the old chapel, was the site of a chapel raised by Bruce for the repose of the soul of his brother-in-law, whom Edward I. had caused to be hanged on that spot. The rampart passed near this building, the walls of which were pulled down to assist in its construction.

5
Dumfries. 200

In the centre of the square, fronted by this edifice, stands a Doric pillar, intended as an expression of the respect in which the public held the virtues of Charles, emphatically designated the Good Duke of Queensberry. This column was reared about the year 1780, by the gentlemen of the county, who certainly did not anticipate, that in less than thirty years, it would be so far dilapidated by neglect, that not a trace of the inscription should remain.

ChuirJin. It has already been stated, that there are two churches. The original parish church, St Michael's, which stands at the south-east end of the town, was rebuilt in 1745, with a tall and handsome spire. It is surrounded by a crowded burying-ground, which contains several remarkable monuments. Here rest the ashes of Burns, over whose grave a splendid mausoleum is about to be reared as a tribute to his genius. The New Church, for it still preposterously retains that designation, occupies the site of the castle which the Lord Maxwell erected out of the ruins of the friary, and its walls are partly built of the materials which once magnificent fortification afforded. This church is also furnished with a steeple. A third steeple, attached to what was formerly the court-house, obstructs itself rather awkwardly upon the high-street, that it may take its station directly in a line betwixt the two first.

We have already mentioned the bridge built by the Lady Dervigillon over the Nith. That venerable fabric, after having withstood the floods of nearly six centuries, though still fit for service, yet having been built before the common use of wheel carriages, was found from its narrowness to be extremely inconvenient. Accordingly, in 1792, the foundation stone of a new bridge, to consist of five wide arches, was laid a little higher up the river; and, in 1795, this new communication with Galloway was opened. The structure impresses the mind with the idea of strength rather than elegance; nevertheless it is handsome.

The academy is a splendid building, in a fine airy situation, erected several years ago by subscription, but for want of funds, left in an unfinished state. It is supplied with masters of eminence for teaching English, writing, arithmetic, and mathematics. French, Latin, and Greek. There is an evident taste in the place for literary information. There are two public subscription libraries, each of which is well furnished; and in 1812, public reading rooms were opened for about 80 subscribers, where there is also an infant library, and where the most esteemed periodical works are taken in.

Among other useful establishments, is the Dumfries and Galloway Horticultural Society, which was formed in this town in 1812, for the purpose of encouraging industry, improvements, and useful discoveries, connected with gardening, by a judicious distribution of prizes. In the immediate neighbourhood of Dumfries, not less than one hundred acres are occupied by gardens and nurseries.

Nor are the inhabitants less distinguished for their benevolence to the afflicted. They have an infirmary, including a lunatic asylum, and a dispensary; and there is also an hospital for the superannuated, widowed, and orphan poor. Both of these institutions are under excellent management. There is also a female society for educating the children of the poor on the plan of Dr Bell.

The town is well supplied with provisions. The weekly market is held every Wednesday, but there are extraordinary markets for black cattle, of which surprising numbers are sold about Whitsunday and Mair-

Dumfries. 201

The chief articles of export are grain, potatoes, and wood; the latter, however, not in large quantities. The articles imported are wine, cork, groceries, iron, foreign timber, slates, lime, and coals. The two latter come from the coast of Cumberland.

Under the authority of an Act of Parliament obtained in 1811, the navigation of the Nith has been greatly improved already; and as the plan is far from being completed, is likely soon to be much more so. Formerly, few vessels of more than 40 tons ever reached the town, and these only at high tides. All above that burthen were obliged to unload either at the New Quay, three miles down the river, or at Gleenapple, which is twice that distance. Now, however, in consequence of the removal of obstructions, improving the direction of the channel, and confining the water, vessels of 150 tons can, under favourable circumstances, bring their cargoes almost to the very doors of those to whom they are consigned; and it is expected, by some sanguine ship owners, that ere long, vessels will be seen there of a much bigger burthen still.

From the date of the earliest documents, the population of Dumfries has been uniformly on the increase. Previous to 1695, one church and one minister were sufficient for the parish. In that year, owing to the augmented numbers of the inhabitants, it was found necessary to make the charge collegiate; and, in 1726, the foundation stone was laid of a new church, at the north end of the town, which was then more than three-quarters of a mile in length.

1811, there were 5907 males, & 4023 females=9930
For most of the historical information contained in this article, the writer is indebted to a manuscript of the late Rev. Dr Burnside, minister of St Michael's church in Dumfries, a copy of which valuable document is lodged in the Gentleman's Library there. See also Statistical Account of Scotland; Hist. of Scotland, by Piscottie, Keith, & Robertson; Peter Rae's Hist of the Rebellion; and Stowe's Hist. of England. (G. T. A.)
DUMFRIES-SHIRE, a border county, in the south of Scotland, adjacent to that of Cumberland, in England. It extends in latitude from 55° 2' to 55° 31' North, and in longitude from 2° 39' to 3° 59' West from London. The counties adjacent to that of Dumfries are, on the north, Lanark, Peebles, and Selkirk; on the east, Roxburgh, and part of Cumberland; on the west, Ayr, and the stewartry of Kirkcudbright: the Solway Firth, on the south of Dumfries-shire, separates it from Cumberland in that quarter. According to the observations of Mr White, mathematical teacher in Dumfries, the latitude of this town, which is the most eminent in the south-western districts of Scotland, is 55° 8' 30".

The territory which is now the county of Dumfries, consists of three larger, and many lesser vales, together with the ridges which divide or intersect them; the mountainous tracts at the sources of the main rivers, Nith, Annan, and Esk; and the open country through which they pass, near the Solway Firth. Out of all these tracts, were formed three ancient and separate jurisdictions, the sheriffdom of Nithsdale, the stewartry of Annandale, and the regality of Eskdale; all which are now under the civil jurisdiction of the sheriff-depute of Dumfries-shire, and his substitute. Formerly, the conterminous districts around this county also were known by other names; viz. on the north, Clydesdale and Tweedside; on the east, Ettrick Forest, with Tiviotdale and Liddesdale, and part of the Border Marches; and, on the west, the ancient province of Galloway, and the district of Kyle.

The Solway, on the south, appears to have been connected with the Roman district-name of the Selgovae, of whom the inhabitants of this county, in the time of the Roman empire, were a part, when the province called Valentinia extended from the Solway to the Clyde.

The figure of Dumfries-shire approaches towards that of an ellipsoid; the greater diameter measuring 50, and the lesser 32 miles. The line of circumference consists of 21 miles of sea-coast, 33 miles of low inland territory, and 120 miles in the mountains; being, in all, 174 miles. Of land-surface, the contents are about 1006 square miles; being, in Scots acres, 512,560; and, in English acres, 644,585. The surface of the waters within the county, consisting of lakes, rivers, and streams, is about 10 square miles.

In the lower part of the county, adjacent or near to the Solway Firth, a gently undulating surface, consisting mostly of dry soil, presents itself, intersected by those rivers and streams which flow into the Solway, diversified also by spots or fields of bough or clay soils, and of peat moss. Farther inland, a few lakes appear, mostly in the central district of Lochmaben. Towards the sources of the principal rivers, a range of mountains environ the county on the north, and form its boundaries with those of Ayr, Lanark, and Peebles. These detach considerable arms, terminating in ridges of less elevation, which divide the river-courses, or form the boundaries of the county on the east and west. The general slope and aspect are to the south, in which direction the principal rivers flow. Thus, on the north side the county is mountainous, and partly also on the north-east and the north-west. The middle districts are separated by lower hills and ridges. Three principal dales open towards the south, and lesser lateral vales communicate with each of them, on either side; the courses of the rivers and streams having tracts of holm or bough lands along their margins. As the main rivers approach the Solway, their separating ridges vanish; and their course for some miles is through an open country, elevated a little above the sea, and exhibiting a surface, not level, but in that wavy form which commonly indicates a light soil, improvable rather than rich, and a country naturally adapted for pleasing embellishment and agreeable residence.

From what has been mentioned relative to the mountains on the north, and ridges of hills which descend as arms from these downwards to the maritime parts of the county; and from the aspect of the mountain faces, and the principal dales towards the meridian sun, it may be supposed that the climate of the vales is comparatively favourable. Situated in the southern extremity of Scotland, and so far west as not to be liable to cold rains or hoars from the eastern quarter, the county of Dumfries enjoys a mild climate. It is, indeed, liable to rains from the south-west, especially in the mountainous districts; but, from the south, it is partially protected by the Westmoreland and Cumberland mountains; and, from the west, by those of Galloway and Ayrshire. On the whole, the climate is both agreeable and salubrious. Few clay boggs of remarkable extent exist in it; and, though considerable tracts of peat bog appear in various parts, and one of uncommon extent near Dumfries, in the maritime district,—the marsh-fever seldom occurs within the county. It is particularly well adapted for the rearing of cattle and sheep; and all the kinds and varieties of corn which are cultivated as field crops in the south of Scotland or north of England, prosper in Dumfries-shire. The soil, however, is not commonly suitable for the bean, nor the climate for the later varieties of the pea, as ordinary crops in the fields.

The mountains of Dumfries-shire do not form any regular continued chain. Black Larg and Corsonnene, in the north-west quarter, are on the confines of Ayrshire; the Lowthers are an elevated group of mountains, on the borders of Lanarkshire. Queensberry, on the same border, stands almost in the central parts of Dumfries-shire, into which, in that point, Lanarkshire makes a deep inroad. This mountain appears like a central giant, sending out his arms in several directions. The most eminent of the mountains is the Hartfell group, on the confines of the shire of Peebles, being the highest land south of the Firth in this island, excepting only Snowdon in Wales. This group includes Hartfell and White Coom in this county, and Broad Law in that of Peebles. Ettrick-pan, on the confines of Selkirkshire, and Lochfell near it, within the county of Dumfries, in the north-eastern quarter, and the hills that separate Eskdale from Roxburghshire, all terminate the list of the principal environing mountains which defend this county from the northern blasts; and, forming an elevated barrier in that direction, give Dumfries-shire a favourable slope and aspect to the south.

Of these mountains, Queensberry has been included in the general survey carried on lately by order of the Board of Ordnance, and its elevation has been ascertained to be 2259 feet above sea-level; the latitude of the summit being 55° 17' 24" north, and the longitude 3° 34' 47" west. The height of Wisp Hill in Wigtown has also been found, and is 1954 feet. The spirit-level applied on the top of Queensberry (allowance being made for curvature and refraction), discovers Lochfell to be fully higher, and the Lowthers and Hartfell consider-
Dumfries-shire.

View from their summits.

Rivers.

The chief rivers of Dumfries-shire have already been mentioned, viz. the Nith on the west, the Annan in the central parts, and the Esk on the east. The course of these rivers is towards the south, and they all pour their waters into the Solway Frith. Among the mountains at or near their sources, the Nith is above 20 miles from the Annan, and the Annan above 10 miles from the Nith. As they descend, they approach nearer each other. The Nith, which rises in the county of Ayr, and runs the longest course, contains also most water, and receives the streams of a more extended tract of country. The Annan passes through a wider vale. The river Esk is confined in its course, and enters Cumberland before it passes into the Frith.

Into each of these rivers, various lateral streams descend, on either hand, opening lesser vales into the principal river courses. The Nith receives the waters of the beautiful river Cluden or Cairn, and those of the Shinnel, Scar, Cample, Carron, Minnuck, Eschen, and Kello. The Annan receives the waters of the Milk, Dryfe, Kinnel, Ae, Wamphray, Moffat, and Evan. Into the Esk descend the streams of Eves, and of Liddel, Tarras, Wauchopie, and Meggot.

The Vale of Nith enjoys the benefit of the county town of Dumfries near its lower, and of the royal burgh of Sanquhar near its upper extremity. It possesses also coal-mines near the head of the vale, and well worked limestone quarries near the centre of it. This valley is naturally divided into three parts, by the approach of the hills near to each other on its banks, in two particular places, forming three sub-divisions of the vale; the uppermost at Sanquhar, the middle division at Closeburn, and the lower at the county town of Dumfries: but every stream that has been mentioned as flowing into the Nith, opens a lesser vale to the right or the left. The vale of Annan contains more champaign or open lands, and is less boldly divided by the hills, than that of Nith; yet the ridges approach each other on either side, particularly in two parts; and various lateral vales open into it on each bank. It possesses lime-quarries in the lower districts, but no lime or coal above. The river Esk passes through a vale, for the most part confined, but opening wider near the borders of Cumberland. Coal and lime are found in the lower parts of Eskdale. Besides the main rivers, the Sark, which is a Border stream,—the Kirkle, which, though it flows in the vale of Annan, is not connected with this river,—and the Lochar, which is a dark rivulet, flowing from the moss of the same name,—all pass directly into the Solway Frith.

Those extensive tracts of mountain lands, which are chiefly in sheep walk, near the sources of the principal rivers, are broken, and pleasantly diversified by the interjacent larger and lesser vales, where cattle also are reared, and crops raised in considerable variety. The sheep-walks of Eskdale are mostly green hills, well drained, though naturally moist, and supporting strong flocks of the Cheviot breed. The sheep-walks of Annandale and Nithsdale contain more of rock and gravel, and are therefore drier, and bear a larger quantity of heath. Cheviot flocks occupy most of the sheep-walks of Annandale; and the forest or black-faced sheep still possess a large proportion of those of Nithsdale. Nothing, however, seems to be wanting excepting shelter for the ewes and lambs, to prepare for the introduction of Cheviot flocks into almost every sheep farm in the county where they are still wanting. These mountainous tracts, having vales interspersed, extend over 17 parishes and 597 square miles of territory, being nearly 1/5 ths of the whole surface of the county.

The midlands contain hills and low ridges, with a large proportion of low situated lands; and they possess a few flocks of sheep, together with a considerable number of black cattle, and a corresponding extent of arable soils. The whole contain 18 parishes, and 322 square miles of surface, being about 1/50 ths of the county.

Maritime districts.

In the maritime district, which is nearly all a low country, above 20 miles long from east to west along the Solway Frith, and about four miles broad from that Frith northwards, there is little waste land except peat-bogs. The soil is, or may be cultivated to great advantage. Considerable quantities of corn of all kinds are produced; and a suitable number of cattle, with some flocks of sheep, of the improved breeds, answering low districts, are also reared. This maritime district contains 86 square miles, being about 1/90 th of the surface of the county.

A territory more adapted for improvement can scarcely be mentioned. Yet it may be truly said, that, with respect to most part of it, this work is hardly commenced. The means, in some parts, especially in upper Annandale, are at a distance; neither coal nor lime being worked there; and the markets are also remote. In various parts, the conditions on which lands have been held, are not well adapted for their improvement. There is no certain and easy market within the county for well fed cattle and sheep in quantities. The market for wool is heavy and ill regulated. Many of the farmers are deficient in capital and enterprise. The system of overcropping for corn still prevails, and that of cultivating rich grass in the pastures and meadows is far too little encouraged.

The population has augmented so much as to furnish hands for the labour necessary in executing improvements, and also an additional demand for produce. In 1755, the inhabitants of the country were returned to Dr. Webster at 39,788; by the public statutory returns in 1801, the number had risen to 54,597; and by the same returns in 1811, this number was farther augmented to 62,783; not including 120 yeomanry in three troops, 400 men in a battalion of six companies, and
DUMFRIES-SHIRE. 195

Dumfriesshire.

719 in each of the two battalions of ten companies, first of the Nithsdale, and, secondly, of the Annandale and Eskdale local militia, in all 1558 men; which, with 284 men serving for this county in the regular militia, amount in whole to 2212 men, as the domestic or defensive force of the county. This number, added to the last population list, raises the total number to 65,023 souls, not including those who serve in the regular army or the navy.

The mineralogical structure of Dumfries-shire has been repeatedly surveyed. Professor Jameson published a survey in 1805, which has been designed as the first part of a general survey of Scotland, was drawn up a plan suited for that purpose. Previous to that scientific survey, the county gentlemen, in 1800, had engaged Messrs. Busby, coal viewers from Northumberland, to make a practical survey; and some directions having been prepared by the late Dr. Walker and also by Mr. Jameson, the county meeting of Dumfries gave instructions to the Messrs. Busby, and they made their survey and report in 1800, which was published by Dr. Singer in the Appendix of his Agricultural Survey 1812. Major General Drom of Mount Annan having suggested these useful undertakings, as proper to accompany the map of the county prepared by Mr. W. Crawford, he also formed a table with sections of the mineralogical structure of Dumfries-shire, which was added to the other engravings on that map, and contains a very distinct and intelligent abstract. But few counties have been surveyed of late years, with more general attention than Dumfries-shire; a great deal of useful information was communicated by the Busbys, and also in General Drom's table, and in the work published by Professor Jameson, all in succession; and yet, after all, the field of investigation appears to be little more than opened. The discovery of coal and lime in various districts where these mineral treasures are much wanted, remains yet to be made; and no roof slate or metallic repositories have been opened in consequence of the late surveys.

Transition rocks.

According to Professor Jameson, nearly the whole of the upper part of this county is composed of transition rocks. Among these, he particularly observed grey-wacke, greenstone, and flinty-alum, or grey-wacke-slate. These rocks he considers the oldest in the county, and the basis of all the newer formations.

Next in point of age he reckons the independent coal formation, which pervades the low part of the country, disposed in strata from the Nith to the Esk, over the transition rocks; or lying in hollows of these rocks, as at Sanquhar, Closeburn near Dumfries, at Whitehill, Balderscrag, Corncockle Muir, Chapel Hill by Moffat, and Canobic.

The newest of the universal formations he states to be the flintz trap, covering sometimes the transition rocks, and sometimes the independent coal formation; and consisting in the lower parts of the county, of porphyritic greenstone and amygdaloid from the bridge of Langholm to Denbie; while, in the upper parts, (as between Wamphray and Langholm,) it lies on the summit of transition mountains, generally in the shape of mountain caps, blackish pitchstone being subordinate to it.

Of that arrangement of compound minerals which divides them into five classes, (viz. the primitive, the transition, stratified or secondary class, the alluvial, and the volcanic,) the first and last classes of rocks do not seem to have presented themselves in this county. The transition mountains are of great extent; the secondary strata run up the three principal valleys to the very bases of those mountains; and the alluvial class embraces a variety of soils, the most remarkable of which are the haugh or holm lands, near the rivers, and some fields of sleech near the sea. The practical coal viewers have not made any other distinction than into the primitive or primary rocks, and the secondary or stratified.

From the rocky faces and broken scars of the principal mountains, their conformation seems to be similar to them all. Wacken and trap are the rocks which prevail with slate of different character. Near the bases of the largest mountains, beds of ferruginous clay appear, and masses of conglomerate occasionally present themselves, with black shistus resembling coal, though not containing bitumen, but smelling of sulphur, as black ore of copper does. Here also chalybeate waters frequently issue in springs.

The mines of Wanlockhead are computed as yielding Lead mines, about L30,000 worth of lead annually, one-sixth of which belongs to the Duke of Buccleuch, as the superior and proprietor. The produce in 1808 was 15,552 bars, of nine stones avoidoips each; and the price for that year was L.32 per ton. It has been said that the mines of Leadhills in Lanarkshire, and of Wanlockhead in this county, which are near each other in the same range of mountains, were opened in consequence of a discovery by one Martin Templeton in 1517; but others believe them to have been open of a much older date; and some think they may have been known even to the Romans, whose public roads passed near those mountains, and who might the more readily have known the veins, as most of them have appeared on the surface. It is the more probable, since two lead bars are said to exist still, which had been worked by the Romans, and are marked with the date and the name of the emperor, the one at Ripley, and the other in the British museum. A drift was opened in search of copper and lead, in the mountains near Hartfell, many years ago, without success.

It is now of particular importance to open slate quarries in the districts remote from the sea. The very superior slates of Lancashire, betwixt prime cost, and land and water carriage, are very expensive. Glenochar is remote, and the slate is rather soft, and not always to be obtained.

Among the secondary strata which are found in most of the lower parts of this county, coal is worked at Sanquhar and Kirkconnel, in the north-western part of the county, towards the head of Nithsdale; and also in the parish of Canoby, in the south-eastern parts, near the lower part of Eskdale. It is unfortunately not found in the neighbourhood of the greatest population; nor at Closeburn, or Kelhead, near the principal quarries of limestone. The upper districts of Annandale and Eskdale, which are very remote from the sea, feel exceedingly the want of coal and lime; the mere carriage of a single cart load of the former now costing at least fifteen, and of the latter twelve shillings. The last boring in this county was lately made in the vicinity of Moffat, in search of coal. It was put down about 100 feet, mostly at the expense of the ordinary inhabitants, and went through various thick seams of red sandstone. This colour has been commonly held as an unfavourable sign of coal; but it has been understood of late, both from concurring facts, and the admissions of men eminent for mineralogical science, that coal does really associate with red sandstone. The
DUMFRIES-SHIRE.

Red sand-stone alternating with coal.

In the bogs of Canoby, where Mr Keir bored to the depth of 148 feet, thick beds of red sandstone were found alternating with what are commonly denominated the coal metals. At Sanquhar, the Bushy's remarked, that in proceeding towards the dip of the seams, a stratum of red sandstone, six feet thick, appeared to overlap the coal metals; and, at Whitehaven, they observed, that the coal appeared to have a connection with that of Workington; that, for a considerable way towards St Bee's Head, there is a great body of red strata, in some places reported from 45 to 60 fathoms, chiefly of the sandstone and shistose description, with some reddish limestone also, all much resembling those of Annan-dale; that at the sea shore, where the seam of coal is 14 feet thick, the workings are 120 fathoms deep, the red strata overlapping the coal metals; and that the present workings below the sea are opposite to St Bee's Head, where the greatest body of the red strata appear, below which is a seam of coal, about 18 inches thick, succeeded by the ordinary coal metals.

These facts, and many others, naturally lead to the opinion, that coal may be discovered below the red sandstone of Dumfries-shire; but that 140 feet cannot be considered as a sufficient depth for a fair trial. Yet none of the late unsuccessful borings have been carried farther; although at Canoby it was beyond this depth that the best workable seam appeared.

The mere existence of coal, however, is not the only consideration to be attended to. In the neighbourhood of Criffle, a mountain in the strewary, but near Dum-fries, the coal metals, and even thin seams of coal, appear; but they are in a disturbed and confused arrangement, probably owing to their approaching schistose rocks in that mountain. Coal appears in various parts, as in Achintaggert-burn, but of inferior quality. The regularity of the seams, facility of working them, quality of the coal, population of the district, means of working pumps by water wheels, and facility of conveyance to other parts, are all considerations of importance; together with the price and value in the place where a seam is found.

The use of lime in this county is very liberal and extensive, not less than 1,500,000 Winchester bushels of shells being used annually, one way or other. This would fully load 100,000 single horse carts; and four-fifths of the whole are computed to be consumed on the land, about 14,000 acres being manured with lime. The lands within the county furnish the greater part of all this; and the remainder is imported by sea, or enters the upper district of Annandale from the Douglas lime-works in Lanarkshire, and the head of Nithsdale from Ayrshire. About 140,000 acres of cultivated land are under the lime husbandry in this county; and in-calcable improvement has thereby been effected in the soil and produce. The total expense is now rising very high, approaching to L60,000 a year for lime as a manure; and on each acre leading to an expenditure of from L.4 to L.5 every ten years, being annually from eight to nine shillings. The prices are also rising; and if it be desired that farmers should drain and lime their waste lands and common pastures, efforts must be made for coal to burn the lime, and for coal and lime also in the remote districts.

The principal of the present lime-works are those of Closeburn and of Kelhead; but other kilns have been opened in various parts of the lower districts of Annan-dale and Eskdale, or in the central parts of Nithsdale. In this latter part of the county, coal is carried down from Sanquhar by land, a considerable distance, to burn the lime; and most of the other kilns are supplied with coal water-borne from England, and subject also to land carriage from the Solway Firth.

The limestone of this county is generally stratified, and contains very thin seams of clay between the strata, which are useful in separating and working the stone. Petrifactions are frequently found in it of different kinds; and sometimes hollows occur in the stone, either empty, or filled with clay. The Barjarg limestone is a continuation of the same that occurs at Closeburn. The brown muir limestone is supposed to extend through most parts of the lower district of Annandale. The Blackwood ridge limestone is mixed with clay, but yields very white and pure lime, and appears to be the same with what is worked also at the Doukins. At Calronlee and High Muir, the stone is trough-shaped. In Eskdale, the coal formation begins at Langholm-bridge, and extends to the Solway Firth; and limestone appears in many different places of this district.

The valued rent is in Scots money, (ascertained in the protectorate or usurpation, and adopted virtually thereafter,) L.158,627 : 6 : 8; which in merks Scots is 238,000, and in sterling money L13,223 : 18 : 4.

The real rents taken from the statistical volumes, and corresponding nearly to the medium year 1795, were L.109,700; and the returns of land rents and of different mines to the tax-office in 1808, were L.219,037 : 10 : 8. But the present value of the lands and mines of the whole county, in open market, is greatly more.

The great western Roman road from Carlisle into Roman Amnandale and Nithsdale, and up these districts to the Castle of Crawford, where the lines meet, having also a branch up Eskdale to Castle Onil, was planned by Agricola; and being executed by his successors, was most frequented by the Roman armies down to the time of Severus. Many remarkable stations occur in the vicinity of these lines of road; and coins and other things have been discovered, indicating that Romans had frequented the country.

Dumfries-shire is now opened up by six lines of Turnpike turnpike roads; five of which are under the direction of the commissioners within the county, having twenty-nine toll-gates, and returning for the year ending at Whitsunday 1811, the gross rent of L.4134, 5s. One important line is now carrying through, executed partly by the commercial interest of Glasgow, and partly depending on subscriptions in this county and on government aid. The district or county roads and bridges, are made and repaired by the converted value of the statute labour, now authorised to be raised as high as 30s. in the 100 merks valued rent from the occupants of land, which, if carried to the maximum, would raise a gross fund of L.3570 a year: in aid of which fund, the county is in use to assess landholders to a moderate sum for bridges; and individuals are also accustomed to subscribe.

Manufactures on a very moderate scale are carried on in carpets, in paper, cotton-yarn, spades, tanned leather, soap, candles, salt, ale, and beer, porter and stockings. Linen is hardly made for sale, though it is manufactured for use. The manufacture of wool is almost lost in this county, and over Scotland in general, for want of correct stapling houses, to assort the raw material.

Commerce is improving; and by the Custom-house Commerce, returns for 1809, there were 493 cargoes inwards, and
DUMFRIES-shire.

287 cargoes outwards; the total of the burdens 29,427 tons.

The royal borough of Dumfries is the county town. The other royal burghs are Annan, Lochmaben, and Sanquhar. Annan is already much improved; but it wants a port. Lochmaben stands in the finest and most open and improvable district in the county, and is likely to be soon improved materially, together with the adjacent country, by means of a canal from the mouth of the river Annan by the line works at Kelhead.

The fine village of Moffat, situated at the base of Hartfell mountain, sheltered from the north and east, and furnished with sulphur and chalybeate waters, and with accommodations for genteel strangers,—is well known. That of Langholm on the river Esk, and of Thornhill on the Nith, are advantageously situated. New villages have been laid out on the properties of Dalswinton, Mount Annan, Kellhead, and Rockhall.

It is not supposed that the woods and plantations of the whole county exceed six or seven thousand acres. Many of the heath ridges appear to have been in culture for corn at a remote period of time; and peat mosses have accumulated in rich forest lands. The Scots pine grows in some of these lands, and it is not considered as interfering with the mountain arms of Dumfries-shire, that intersect it from north to south, are admirable subjects for the planter to work in.

The total number of sheep is supposed to exceed 200,000. Of these mountain flocks, the greater part are now of the Cheviot breed, and next in number are those of the black-faced breed. Lesser flocks of New Leicester sheep are reared in the lower farms, by the most respectable improvers. A few small parcellers, also, of the Spanish, and some of the Merino blood. The cattle are mostly of the Galloway race, and rise in number to about 30,000. It has been found, that so many pigs are now reared as to furnish bacon for export from the county, to the extent of nearly L.50,000 a-year. The returns made in gross from the milk cows and other cattle, and from the sheep in the common walks and lower districts of Dumfries-shire, have been computed as rising above L.300,000 a-year. The gross produce of the crops raised on 150,000 acres of cultivated soils, is considered as rather more than all the returns from live stock; the lands in pasture not being included.

The number of the freeholders on the last roll was 74; and that of the commissioners of supply about 198. There are 20 deputy lieutenants to assist the lord or vice-lieutenant in arranging and maintaining the domestic force of the county; and the justices of the peace exceed 140.

The property taxes levied in this county for the year 1808, after all deductions and abatements were made, amounted to £31,709. 1s. 7d.; being from two to three times the whole valued rents at the time of the usurpation.

Wheat is now cultivated throughout all the county, except in the very highest parts of it. It is believed that in remote times, this valuable grain was cultivated in quantities in Dumfries, Galloway, and Ayr. Oats are in high perfection, raised in all parts of the county. Potatoes are almost the staple produce. Sown grasses and meadow hay are abundant.

The principal articles of export are, in lead, cattle, wool, grain, and potatoes; and those of import consist mostly of coal, slates, and foreign pine timber, with groceries of all kinds, wine, and iron.

The most venerable castles are those of Caerlavock, Lochmaben, Achnasc, Morton, Sanquhar, Comlongan, Torforth, &c.; and the chief houses are those of Drumlanrig, Ruchill, Dalswinton, Castlemilk, Closeburn, Springkell, Blackwood, &c.

The fisheries in the rivers are greatly failed of late years. This failure is ascribed to the killing of the spawning fish in these rivers; and a new act to prevent it was lately obtained. But it proceeds very much from the almost entire capture of the fish as they move up the Solway, in the numerous nets that are placed there in the salt water.

Fuel, in various parts of Dumfries-shire, is expensive; coal being remote, and the peat-mosses requiring much labour, time, and expense.

The common lands, in this county, have been either altogether or for the most part divided, and are now either improved, or in process for that purpose. A great proportion of the marches of conterminous estates have also been straightened and fenced; and enclosure and subdivision are going forward in most of the farms.

(See Botany, p. 78.)

DUMOS.E. See Botany, p. 78.

DUNBAR is situated at the mouth of the Frith of Forth. It consists of a large and spacious street, extending from north and south, and containing many good houses, which are in general three stories high. The principal public buildings are the Town Hall, the Church, and the New Inn. The Town Hall is a wretched building, with a paltry spire in a state of extreme decay. The church is a long mean building, with a square tower at its west end, having small turrets at each angle, and a larger turret in the centre, by way of a spire. The New Inn is one of the best buildings of this kind in any of the provincial towns of Scotland. It is three stories high, large and commodious, with suitable stables, &c.

At the north end of the principal street stands the residence of the Earl of Lauderdale, with its back turned most contumaciously to the town, and forming the actual termination of the street. The front of this house is built of fine freestone. It has a semicircular porch supported by six columns of the Ionic order. The wings, which are unusually large, are higher than the body of the house, and appear to contain the public rooms. The whole establishment runs along the front wall.

The harbour of Dunbar is far from being large. It consists of an inner and an outer harbour with a dry dock. In the inner harbour there is generally 16 feet of water at stream tides. The outer harbour is defended by a small fort, mounted with several cannon, and standing upon a rock of columnar sandstone.

The ruins of the old castle of Dunbar stand to the north east of the harbour. It is situated on several projecting rocky promontories, hollowed out by the action of the sea into huge caverns, sometimes open above, and crossed by natural arches of rock. It has a very interesting and unusual appearance, and is particularly deserving of notice. (ed.)

DUNDEE, a sea-port and manufacturing town in Scotland, is situated on the north bank of the Frith of Tay, and within the county of Angus or Forfarshire. In 1811 the population amounted to 29,716, exclusive of seamen and militia, being an increase in ten years of nearly 4000; and the seamen belonging to this port amounted at present to about 1273. The town of Dundee is far from elegant; but there are many handsome public buildings and private houses in it. The High Street is an oblong 360 feet in length, by 100 feet broad; the other streets diverging from it are generally narrow. A little to the west of this street stands the
Old Church, having a large square Gothic tower 156 feet high; on the south side of it the town-house is built upon the site of an old church, and contains a guild-hall, court-room, prison, the Dundee bank, &c. At the east end of the square there is a handsome trades hall. St Andrew's Church is an elegant new building, with a spire 139 feet high. A large infirmary has been for a considerable time established; and a lunatic asylum, planned by the late Mr Stark, is partly finished. The other public buildings of any appearance are a small theatre, and a new Gothic chapel for an Episcopal congregation.

Dundee is a royal borough. It has enjoyed privileges as ample as those of any borough in Scotland, since the reign of William, which began in 1165; and these were recognized by a charter of King Robert Bruce, dated March 14th, in the 22d year of his reign. The privileges were greatly increased in subsequent reigns, until, in that of James VI. in January 1601, they were all confirmed, and last of all ratified by Charles I. in what is called the great charter, which bears that all its articles were ratified in parliament, 1641. The government of the town is vested in a council of twenty persons, who, in the ordinary way throughout Scotland, choose a provost and four bailies annually. The revenues, of which the magistrates have the management, amount to about 4000 per annum.

The trade of this port is very considerable, and although of late years the actual exports and imports, owing to the general obstructions of commerce, afford no adequate idea of the tendency to increase, we shall state them for the year 1813, with this remark, that the direct imports and exports bear no proportion to the goods carried to and from Dundee coastwise, which are not here included.

In 1791 the exports to foreign ports, entered at the custom-house, were 72,777 tons. The imports same year, 2839 1/2 tons of sundry goods; 1086 hogs. of linseed; 1700 loads of fir timber; 6300 fir bales; and 13,100 fir deals. In the same year the goods sent coastwise were 7,842,000 yards of linen, 150,752 pounds of thread, 280,000 yards of sailcloth, 65,000 yards of cotton bagging, barley 23,917, and wheat 5007 quarters. The goods brought coastwise, in that period, were cotton wool 35 tons, tea 47,745 pounds, 1080 hogs. of porter, 23,021 tons of coals, sugar 5834 tons. There are at present 30 vessels of different sizes belonging to Dundee, employed in the foreign trade, 4901 tons; 116 ships, 7384 tons in the coasting trade; and 8 ships in the fishing trade, 2624 tons; making the whole tonnage of shipping belonging to the port 14,890.

The same causes which of late have had a prejudicial influence on trade, have also operated on manufactures, and those of Dundee can only be correctly viewed by taking a retrospect. The linen manufacture has been long carried on in it to a great extent. Between 1788 and 1789, the quantity of Osnaburghs stamped amounted to 4,249,653 yards, valued at L108,782, 14s. 2d.; and supposing a fourth of this quantity to have been brought from the neighbourhood to the Dundee stamp-offices, the quantity made in the town and vicinity would be 3,181,990 yards, worth L80,557, 0s. 8d.

We add a note of the stamped linen cloths for the last four years.

Besides Osnaburghs, there is a great deal of canvass for shipping manufactured, probably nearly 800,000 yards annually. This, however, is mostly a war manufacture. Besides bagging, diapers, and various coarse linen cloths, the cotton manufactures have been carried on to a considerable extent. A woollen cloth manufacture has recently been established. White and coloured linen threads, and every other species of manufacture now generally introduced into Scotland, have obtained a footing in Dundee, and are carried on with as much spirit and success as in other parts of the country.

As connected with the trade and manufactures of this town, we may notice the banks, viz. the Dundee, New, and Union Banks, which are local, and a branch of the British Linen Company.

This town has made a figure in the history of the country. It was twice taken by the English in the reign of Edward, and retaken by Wallace and Bruce, by the latter of whom the castle was demolished. It was taken and burnt by Richard II. and again in the reign of Edward VI. of England. The Marquis of Montrose took it by assault, and it was saved from pilage by the covenanters. It was lastly taken and entirely pillaged by Monk, in Cromwell's protectorate—

one sixth of the inhabitants having been destroyed on that occasion, and all the soldiers loaded with immense booty. Wallace, the Scottish patriot, is said to have been educated at the school of Dundee, and to have commenced his achievements by killing the son of the English governor.

Dundee is a Presbytery seat. There are eight clergymen of the established church, (two of the charges are collegiate,) who officiate in four churches and three chapels of ease. In one of the latter, the clergyman preaches in Gaelic, although very few understand that language. The stipends of the clergy are very inadequate. The dissenters are divided into the following classes: two congregations of Burghers, two of Antiburghers, two of Relief, two of Glassites, and two of Episcopalians. Baptists, Methodists, Bereans, Independents, Unitarians, and Roman Catholics, have also meetings. The Halkinute Independents had a large house, capable of containing 2600 people; but it has been lying waste for several years. The means of education are, 1st, An academy, which is so far a charitable institution, that at least L300 per annum is mortified for the education of boys and girls, the former of
The Abbey, of which nothing but the ruins now remain, is another interesting relic of other times. It was one of the earliest and richest religious houses in Scotland. It was founded as a monastery by Malcolm Canmore, for the monks of the Benedictine order, completed by his son Alexander I. and dedicated, with its church, to the Holy Trinity, and St Margaret, the queen of Malcolm. It was governed by a prior till the reign of David, who converted it into an abbey; and was at one time so magnificent and extensive, that "three sovereign princes, with all their retinue, might have been lodged conveniently within its precincts." Its revenues were derived from places at a considerable distance; but it suffered with the ravages of the reformation, with the other monuments of superstition and royal prodigality. The Abbey was nearly burnt down in the 14th century. Edward I. wintered at Dunfermline in 1303. The church and some cells which had been spared, were, however, nearly demolished in 1500, by the reformers; and the Abbey being erected into a temporal lordship in 1593, and bestowed on Queen Anne of Denmark, all that now remains of this once splendid ecclesiastical edifice, is a part of the great church, built by Malcolm, and the rubbish and ruins which surround it. The part of the church which is still preserved, is occupied as a place of worship. Adjacent to the church, the cemetery of many kings of Scotland is pointed out; and we learn from Sir Robert Sibbald's History of Fife, that the following royal personages are here interred: Malcolm III., Queen Margaret, King Edgar, Alexander I. Sibilla his queen, Henry III., Edward, David I. his queen Margaret, Robert I. his queen Isobel, Edward II. son of Malcolm III.; his brother Etheldrade, earl of Fife; M'Duff, earl of Fife; Constantine, earl of Fife; William Ramsay, earl of Fife; Thomas Ilandel, earl of Murray, governor of Scotland. Robert the Bruce, the most illustrious of our Scottish kings, is also said to be buried at Dunfermline. But all marks of royalty are obliterated from their graves.

The manufactures of Dunfermline are principally diaper and damask, for which this town has long been distinguished. A few years ago, the annual receipt from the sale of these kinds of cloth was calculated to amount to L.150,000; but of late, a great diminution has taken place. The manufacturers in Dunfermline, and its immediate vicinity, who, in September 1813, amounted to 1114, were, until within the period alluded to, employed exclusively in the manufacture of diaper and damask, but many of the operative weavers now receive work from Glasgow, and other places, and some are still altogether unemployed. Great improvements have been made in the Dunfermline branch of manufactures, and there are at present many persons employed in it. For a long period, the goods manufactured were chiefly bought for the London market, by people who came and purchased them on the spot; but for the last twenty years, great quantities of them have been disposed of in the usual way, by the manufacturers going to London, and other places, and receiving orders. Previously to 1749, it was customary to weave ticks and checks during the winter months; but since that time, until of late that the cotton goods for manufacturers in Glasgow, &c., have been woven, nothing, comparatively, but damasks and diapar and damask have been made in Dunfermline.

Dunfermline is the seat of a presbytery; and recently a sheriff-substitute has been appointed, and holds courts for the administration of justice in the western district.
DUNFERMLINE

DUNFERMLINE

DUNKIRK

DUR

DURAND

of Fife. The magistrates also exercise a jurisdiction
consistent within burgh. Besides a parish church, which
is a collegiate charge, there are various places of public
worship, and a great variety of sects: Ralph Erskine, a
leader in the secession from the established church of
Scotland, in 1740, was one of the ministers of Dunfer-
mline. There are a chapel of ease, a relief meeting-house,
two Burgher and two Antiburgher houses, two congrega-
tions of Baptists, and one of Methodists. There is
no parochial school; but a grammar school, the patron-
age of which is in the Marquis of Tweeddale, on the
recommendation of the town council, has long existed in
the burgh. Besides the doctor of the grammar school,
there is a "master of the song," or precentor, who
may teach church music, the English language, and arith-
metic, also under the same patronage. But these means
of education have been found too extremely deficient, that
there are several private schools in the town; and the
council, guildly, and most respectable inhabitants, have
lately united in subscribing liberally for the purpose
of erecting and endowing an academy suitable to the place.
A master has been chosen, but the arrangements are
not yet completed for settling the Establishment. The
Lancastrian system of education, in a modified shape,
has been introduced with success; and there is one
gratis school for the instruction of poor children. There
are three subscription and one circulating libraries in
Dunfermline; two subscription coffee-rooms, and various
institutions of a charitable character, the particular
objects of which are partly of a permanent and partly
of a casual description. The poor, of whom few beg,
are supported by the contributions of the hiritors, and
the collections at the church doors; but a great deal is
done to prevent the increase of parochial paupers, by
means of friendly and other benevolent societies. In
1812, the money given by these, chiefly to poor house-
holders and distressed families, amounted to about
L.1500. A guildhall has lately been erected, but is not
yet finished. It is a handsome building, with a spire,
and will contain rooms for public purposes, an inn, &c.
There are eight fairs in the year, and two weekly mar-
ets, one for the sale of grain, and another for butter,
eggs, &c. There are branches of the bank of Scotland,
and the British Linen Company; and four agencies for
insurance companies against fire. Formerly there was
a considerable number of breweries, and a distillery;
but there are now only five common brewers, three of
whom make strong ale and porter. The town is amply
supplied with water, brought in pipes about two miles.
The streets are well lighted and paved; and many of the
houses comfortable and well built. Coal is abundant,
good and cheap. There is one good inn, and above
100 of an inferior description. The situation and
vicinity of Dunfermline are extremely pleasant. See
Statistical Account of Scotland, &c. (A. P.)

DUN. See Agriculture Index.

DUNFERMLINE, or DUNKERQUE, in Dutch and Flemish
Brabant, a considerable sea port of France, in the
department of the North, 50 miles north-east of Calais.
The name denotes the "church on the Downs, or sand
hills," and the place is of great antiquity. It belonged
for several centuries to the Earls of Flanders, and
passed, in the 15th century, to the House of Austria.
It remained under the Spanish branch of that House a
considerable time, but changed masters more than once,
in the war in the Low Countries carried on in the mi-
nority of Louis XIV. Cromwell having taken part
against Spain, and having assisted the French in ob-
taining possession of Dunkirk, it was put into his
hands, and its fortifications considerably extended by
him. It remained, however, only four years in our
possession, Charles II. selling it, in 1662, to Louis XIV.
for the sum of L.209,000 sterling. That ambitious
monarch expended large sums in strengthening its for-
tifications, so that Dunkirk afterwards became the seat
of very formidable annoyance to the English commerce.
It is said, that in the war of the Succession, the prizes
brought into Dunkirk exceeded the value of a million
sterling; a loss of such importance, that, at the peace
of Utrecht, our ministers made a point of stipulating
for the destruction of the fortifications, and even of the
harbour. This accordingly took place, in a considera-
ble degree, in the year 1713; but though, in the sub-
sequent treaties of 1748 and 1763, similar stipulations
were inserted, the French contrived to evade their ex-
ecution, and the British ministers have been disposed
to consider the insertion of the article as little else than
an expedient for acquiring popularity. Since the
American war, the French have been at liberty to
improve the harbour and fortifications as they thought
proper. It is generally thought, that the Duke of
York might have succeeded in taking possession of this
place in the autumn of 1793, had his operations been
properly combined. Rechard taking his account from
the Terrier office, (le Bureau de Cadastre,) makes the
population of Dunkirk to be 16,832. It may be taken
at about 22,000. The houses are built of white brick.
The communication between the harbour and the in-
terior of the town is by a quay, which is very long and
solid. The rope yard and sailors' magazine are two
buildings, each of nearly 600 feet in front. The bar-
racks are beautiful. There is here a public school for
teaching mathematics and hydrography. The roadstead
of Dunkirk is at the distance of a mile and a half north
of the town, and lies within a sand bank, which runs
parallel to the shore for an extent of nearly five miles
in length. Of late years, it has suffered in point of
trade in the same way as other towns in France, and
its inhabitants have little other occupation than that of
privateer trade, and of a few inland manufactures, such
as glass, ropes, leather, delf ware and starch, &c. In
the time of peace, it will, in all probability, enjoy a considera-
ble foreign trade, and might be expected to employ nearly
200 merchantmen, and 2500 or 3000 seamen. It is
the native place of the celebrated Jean Bart. E. Long.
2° 7', N. Lat. 51° 2'.

DUODECIMAL of a Tone, in Music, (,) is an
interval which Aristoxenus, according to Dr Holder,
constituted as a degree, or common-measure for inter-
vals. It is \(\pm 8.60545 \times m\), or \(8.60545 \times m\); its
common logarithm is .957372,8980 = .0141063 in
Euler's log's, or decimals of the octave: = .790117 x
= 8.607307 \times \Sigma, &c. Some of the ancient writers
on music seem to have assumed, that this interval was
the same with \(\pm 1\) of the minor fourth, but which is
\(8.489514 \times m\), \(9.95833,7545\) in common log's;
and others, that it was the same with \(\pm d\) of the octave,
but which is \(8.522869 \times m\), \(9.958190,2784\). These
differences, though so small apparently in these small
intervals, are nevertheless sufficiently great, when often
repeated, in composing or calculating of intervals by their
means, as to render them very unfit for their intended
purpose. See Common-Measure of Intervals. (c)

DURA MATER. See Anatomy.

DURANTA, a genus of plants of the class Didynamia,
and order Angiopermia. See Botany, p. 255.
DURER, ALBERT, a celebrated German painter and engraver, was born at Nuremberg, A.D. 1471. In the shop of his father, who was a goldsmith, he made his first essays with the pencil; but was taught by an inferior artist named Martin Hupe, to manage colours, and engrave upon copper. When he was about 20 years of age, he began to exhibit some of his works to the public; and soon acquired great celebrity by his engravings. He was one of the first improvers of that art, which he carried to a high degree of perfection; and, excepting his contemporary Michael Angelo Buonaroti, he had no equal during his life. He possessed an inexhaustible fund of designs; and, in order to execute them more expeditiously, he engraved many upon wood. His prints are, of consequence, extremely numerous, and were rapidly bought up as soon as they were thrown off. Besides the excellence of the execution and design, they possess a recommendation, which was not common among the productions of those times, namely, that they are entirely free from obscene representations. One of his best engravings is that of St Eustachius kneeling before a stag, which has a crucifix between its horns; and the principal merit of this piece is supposed to consist in the beauty and variety of attitude imparted to the dogs. He did not produce many paintings; and few of them are now to be seen, except in the more rare collections, or in the palaces of princes. One of the most eminent of these is his painting of Adam and Eve in the palace of Prague, which Gaspar Velius has celebrated in the following couplet:

Angelas voserns, miratus icti, ab horro,
Non ipsa forma; vis ego depurata.

He was well skilled also in statuary, architecture, optics, and geometry; and wrote several treatises upon these subjects, which were published after his death, after having been translated from the original German into the Latin language. He enjoyed the patronage and esteem of the Emperor Maximilian, who bestowed upon him a handsome pension, with letters of nobility; and he continued to experience the liberality of Charles V. and of his brother Ferdinand, king of Hungary. He was for many years the chief magistrate of his native city; and, being in easy circumstances, practised his art more as an amusement than a profession. He lived, however, in a very frugal style, and with all the appearance of poverty rather than of wealth; but was a man of cheerful dispositions, and highly agreeable in conversation. Distinguished, in short, by the mild virtue of his character, as well as by the extent of his genius, he was highly respected during his life; and died at Nuremberg in 1528, where his friend and patron Pircheimer, has honoured his memory with a suitable sepulchral inscription. See Melchior Adams in vitis Philos. German; Vasari de Pittori; Sandrart, Pinxit, &c. (q.)

DURHAM is a county town in the north of England. Its form is nearly that of an equilateral triangle; the eastern side, from its southern extremity at Stockton to the mouth of the Tyne, measuring rather less than the distance of two points from its western extremity, where it joins the counties of Cumberland and Westmoreland. It is situated between the latitudes of 54° 29' and 55° 3'; on the north it is separated from Northumberland by the rivers Tyne and Derwent; on the west from Cumberland and Westmoreland, by the Crookburn and the Tees, and by barren hills and moors; on the south and south-east, from Yorkshire by the Tees; and on the east it is bounded by the German Ocean. The greatest extent of the county, from Shields in the north to Stockton in the south, is rather more than 36 miles; and its greatest breadth, from the peninsula of Hartlepool on the east to the mouth of the Crookburn on the west, where the three counties of Durham, Cumberland, and Westmoreland unite, scarcely reaches 45 miles. Its circumference is about 186 miles, and it contains about 582,400 acres. It is divided into four wards: Chester ward, which contains three divisions; Darlington ward, which contains the same number of divisions; and Easington and Stockton wards, each of which contain two divisions. But besides these, part of the county of Durham lies at the north-eastern extremity of England, separated from the main body of it by the whole length of Northumberland. This detached portion is divided into two parts, Islandshire (so called from its comprehending Holy Island,) which commences a little to the north of Bamborough, and runs along the sea coast, and for seven or eight miles inland, as far as Berwick upon Tweed; and Norhamshire, which lies to the west of Islandshire, and runs up Tweedside, nearly as far as where the Till falls into that river. These two detached portions of Durham contain about 72 square miles of good land, well cultivated. This county pays three parts of the land tax, and provides 400 men for the militia. The natural districts of Durham are not very distinctly marked; nevertheless the sea coast may be distinguished by a flatness and tameness of surface, when compared with the centre parts of the county; the banks of the Twees by lowness of situation, and productivity of soil; the moorlands, which occupy the western parts of the county, on the contrary, are characterized by elevation and barrenness; and the interior is marked by the irregularity of its surface, and the diversity of its soils, comparatively with the rest of the county. The principal vale land consists of the Vale of Stockton, which is well defended by the round, prominent hills, which rise about nine miles northward of the Tees; the flat vale land spreading seven or eight miles from that river. The central district is the largest of the natural districts, commencing at the foot of Gateshead-fell, and extending southward as far as the vale of Stockton: the sea coast district bounds it on the east; and the moorlands, with the valley of Walsingham, on the west. The general appearance of the moorlands of Durham is similar to that of the moorlands of Yorkshire and Northumberland. It is crossed by that ridge of hills, which have been not unaptly called the Pennines of England, though none rise very high in this county. From this description of the face of this district, it will be seen that the general aspect of the county is hilly and naked. As it extends from the sea coast nearly to the top of Crossfell, which is 3400 feet above the level of the sea, the climate of Durham must vary very considerably. In favourable seasons, and early situations, the harvest commences about the middle of August; but when the seasons are cold and wet, little corn is cut, even in the low and sheltered parts of the county, before September; and not unfrequently, in the western parts, it is protracted till the beginning or middle of November. In the spring, cold north and easterly winds prevail; these sometimes continue till the beginning of June, and are succeeded by south and westerly winds, bringing much rain; but the heaviest falls of rain and snow are from the south-east.

Climate.
The soil, in the south-east part of the county, is for the most part a strong fertile clayey loam; to the westward of this, and northward, near Sunderland, is a poor unfertile clay, suitable neither for corn nor grass. The vale lands of the Tees, Skern, and Tyne, consist of dry mellow loams, rather strong; the vale lands of the Wear are of a more friable and sandy nature. There are two districts of limestone; the eastern, beginning at Sunderland, and stretching to Mornington, is dry, but not very productive; whereas the soil on the western limestone, near Stanhope, &c. ranks among the best grazing lands in the north of England. A variety of soil, very thin, and lying on an impervious yellow clay, is found in many parts of the county, to which, from its being apt to throw out the plants of wheat, &c. when the water which lies on its surface is frozen, the appropriate name of water shaken is provincially given. Peaty soils, incumbent either on yellow clay, or white sand, prevail in most parts of the western division of the county. The principal rivers which flow into the sea, are the Wear and the Tyne; the Tyne is more generally considered as a Northumberland river. The Wear rises in those vast moors which separate Yorkshire from Durham, Cumberland, Westmoreland, and Northumberland. It runs at first to the south-east; at Bishop Auckland it turns to the north-east, and after nearly surrounding the city of Durham, it flows northward to Chester-le-street, and then inclines a little towards the east, till it falls into the sea at Sunderland. The Tees finds its source in the same wild range of moors which give rise to the Wear, but considerably to the south of that river. Its course is nearly parallel to it; at first it rather inclines to the south-east, but when it reaches below Darlington, it turns abruptly to the north-east, and falls into the sea below Stockton. Teesdale, through which it flows, presents a long winding stripe of fertile land, surrounded with some of the wildest districts in the kingdom. Below Rokeby, the Tees receives the Greta from Yorkshire. To the northward of the Wear, in the same range of moors, the Darwent takes its rise; at first it pursues an easterly direction, but afterwards inclines more to the north as it approaches the Tyne, into which it falls a little above Newcastle. The rivers of Durham are not of very much advantage to its internal navigation; though the Tees might be rendered much more so than it is at present. A little below Stockton its navigation is very tedious, and often difficult, by reason of an extraordinary peninsula; for though the neck of land between the two parts of the river is only 200 yards, yet the course of the river is above 2 miles. As, however, an act of parliament has been obtained to make a cut across the narrowest part of the peninsula, and the work is actually begun, it is to be hoped that this impediment will soon be removed.

In this county there are some very large estates; but the most common rentals are below L.1000 a-year. The tenures are freehold, copyhold, and leasehold; the southern part being mostly freehold. A third part of the county is supposed to be of ecclesiastical tenure: they are considered as copyholds of inheritance. If the copyholder, however, die with the legal estate vested in him, the estate will go to the heir-at-law, as in the case of no will in freehold, except that the widow, instead of her thirds, is entitled to the whole for her life. The church leases are either for twenty-one years or three lives. Other leases are for three, five, or seven years, a few for twelve or fourteen; and many farms are let to tenants at will. The largest farm in the county does not exceed 1000 acres. There are a considerable number from 150 to 400; but the greatest part of the county is divided into farms from 150 to 50 acres. The best grazing pastures in the middle and eastern parts of the county let from L. 2 and L. 3 per acre; in the western, for 30s. and 50s. Arable land lets considerably lower. Of the houses of proprietors, Raby Castle, the seat of the Earl of Darlington, is an ancient, magnificent, and noble edifice; and Lumby Castle, belonging to the Earl of Scarboroug; Auckland Castle, the episcopal palace of the Bishop of Durham; and Brancepeth Castle, are also remarkable structures. Of the other buildings in the county, some of the bridges only deserve particular notice or description: Wear Bridge, over the Tees, is very singular in its construction; it is a wooden bridge, laid upon iron chains, which are firmly fixed in the rocks on each side of the river. From rock to rock the width is about 70 feet. In order to keep the bridge steady, and to prevent its vibrating, chains are also fixed on both sides, at the distance of about a third of the length of the bridge from each end; and the ends of these chains are fastened to the rocks. Although the iron bridge over the Wear, at Sunderland, has been already described under the article Bridge, yet a very brief account of it may not improperly be given here. It was built in 1796 and 1798, from a model upon a new construction, of uniting hammered iron with cast iron. The arch is a segment of a circle, the span of which is 236 feet, and the versed sine 34 feet. The breadth of the passage on the bridge is 32 feet: the height from the river, at low water, 100 feet; so that vessels may sail under it without striking their masts. It cost in building L. 27,000; and the average yearly amount of the tolls is L. 2030. The weight of cast iron employed in it is 214 tons; of malleable iron 46 tons: in all, 260 tons.

Durham is more distinguished for its grazing than agriculture. Its arable husbandry. The produce of wheat upon good land cannot be estimated higher than between twenty and thirty bushels per acre. As barley is seldom grown, except upon soils drest kindly, the produce of it is larger, viz. from thirty to forty bushels. Oats are grown on a great variety of soils; and as they also form the principal grain-produce of the western or moory part of the county, the average return per acre varies very much; probably it may be estimated at from twenty to forty bushels. Of beans, from fourteen to 20 bushels. Pease seldom succeed, and their produce cannot be rated higher than from eight to twelve bushels per acre. The produce of the hay-lands is not great; some indeed yield two tons of hay per acre, but in general the produce is below half a ton. The woodlands are not of any considerable extent; and though the soil in many parts is peculiarly adapted to the oak, this tree is seldom met with. The ash is much more common. The banks of some of the rivers, however, are adorned with timber. As the materials for making roads are good and abundant, the roads in this county are in general excellent, except in the western parts, where the township roads are narrow and ill-constructed.

Tees water has long been famous for its breed of cattle: They are of the short horned kind. The first attempt to improve them, was by introducing a bull from Holland; but this did not succeed. Mr Bakewell's mode was then followed, and, by judicious selection and crossing, they have been brought to a high state of perfection. Many of them have been remarkable for fat
The celebrated Durham ox was bred by Mr. Charles Collins of Kellon, in the year 1796. His form in every respect was nearly perfect; and as he shewed an early disposition to take on fat, great attention was paid to him. At five years old he was deemed so surprising an animal, that he was purchased to be exhibited as a show for £140, and soon afterwards £2000 were offered for him. He was killed in 1807; and, notwithstanding his being carried so much about for exhibition, yet he weighed upwards of 180 stone, 14 lb. to the stone. The lower parts of this county were formerly remarkable for their large breed of sheep: They were, indeed, the largest in the kingdom; many of them weighing from 50 lb. to 60 lb. the quarter. Some of them were nearly the height of a Shetland pony. But these sheep fell out of repute, when the Tees water farmers (who are the principal and most intelligent graziers in the county) turned their attention to Mr. Bakewell's breed, which is now the prevailing and favourite one in this part of the county. Besides these, however, there are heath sheep, which are distinguished by their black and mottled faces, black legs, and coarse wool. They are mostly found in the western district, on the borders of the moors. Their wool is long and coarse; the average weight of it about 4 lb. In the south-east part of Durham, as well as in the opposite district of Yorkshire, a breed of horses has long been famous, known by the name of Cleveland bays. They are supposed to be the original stock, from which the old English coach horse, stronger hunters, and road horses spring. They are remarkably good draught horses. Their form is very compact; their legs short and sinewy; and they are remarkably strong and active, frequently going sixty or seventy miles for coals or lime in twenty-four hours.

The botany of Durham affords several rare and beautiful plants, among which the burnet rose and the gentiana verna may be particularly enumerated. They are both met with in the neighbourhood of Winch Bridge. The latter, till it was discovered here, was not known to exist in Great Britain. But this county is more interesting to the mineralogist than to the botanist, as its mines are various and valuable.

The mineralogical districts are pretty well distinguished. In entering the county from the west, we immediately meet with the lead district, which stretches the whole breadth of it in this part, and extends to the east, as far as a line drawn from Allerdaleford nearly to Barnard Castle. When we pass this line, we enter on the coal district, which is more irregular in its form. Interposed between it and the sea, at least from Morton, a little to the north of Whitburn, is the principal limestone district. There are also other limestone districts: on entering the county from the south, at Piercebridge, we meet with it. Another lies farther north, on the ridge extending from Houghton to Aykley. Limestone is also found in the lead mine district.

The coal district occupies a space of twenty-two miles in length, and eleven and a half in breadth, and contains about 160,000 acres. The collieries are divided into "water sale" and "land sale": the former occupy about one-third, the latter two-thirds of the district. As, however, there are several parts in which no coal is found, or at least where it is either thrown out by dikes, or lies so low as not to be workable, the actual district of workable coals cannot be estimated to occupy more than 160,000 acres. The strata are very various in thickness, and in the quality of the coal. The land sale collieries lie in the south and western parts of the district, the water sale in the northern parts. It is calculated, that in the water sale collieries 1,333,000 chaldrons are wrought annually, which employ 701 men; and that in the land sale collieries 147,080 chaldrons are wrought, which employ 382. The kelleymen employed on the two rivers of Tyne and the Wear are 3257; so that the total number of chaldrons is 1,480,080, and the number of men employed is 10,630. It is calculated, that if the seamen who navigate the collieries which sail from Sunderland are taken into the account, the number of men employed in the coal trade on the river Wear are 15,000; and their families being computed at 11,000, there will thus be 26,000 persons supported by the coal works. As each chaldron of coals weighs 28 cwt., and a cubic yard of coal weighs a ton, there are 1,806,200 cubic yards wrought yearly for exportation, which occupy 112 acres. The average thickness of the workable seams is about five yards. The strata seldom lie horizontally, but generally at a small angle; and whatever the angle of inclination in one seam may be, let there be ever so many, they have all the same inclination. The fall dip is generally in a south-westerly direction. The dikes are divided into up-cast dikes and down-cast dikes, as the strata are cast up or down. The gut of the dikes is mostly filled with clay. The most remarkable dike is the whinstone dike, upon Cockfield dale: it runs nearly in a south-easterly direction: it is a "down-cast" to the north, of three fathoms. The breadth is seventeen yards, which is occupied by whinstone, that appears to have been in a state of fusion when it filled up the fracture. This is inferred from the appearance and nature of the coal, to the distance of some feet on each side of it, which is turned into a sooty substance, and becomes cinder as the distance from the whinstone increases. By degrees, however, it assumes the natural appearance of coal, and possesses all its proprieties. This takes place completely about fifty yards from the whinstone. Considerable quantities of ore of sulphur, of a beautiful bright yellow colour, and of an angular form, is found on the under surface of the stratum, lying on that part of the seam which is converted into cinders. The water burns clean without smoke, and affords a durable heat. In a dike somewhat similar to this, near Durham, some small quantities of lead ore have been found. The coals are brought out of the pits on machines drawn by steam; and from the pits to the water on waggons, which run on iron railways. It may not be improper here to notice an ingenious contrivance by the late Mr. George Dixon of Cockfield, in this county, for conveying coals, or other bodies of nearly the same specific gravity, by water without boats: "The specific gravity of coals not being much greater than water, he calculated the declivity necessary to give water a sufficient force to overcome the excess of weight that an equal bulk of coals had over an equal bulk of water, and laid a cut made upon Cockfield Fell, about four feet wide at top, and three feet deep, with such an inclination as to give the water the necessary velocity. When a cart load of coals was put into it, they swam, or were carried gently by the water into a reservoir, or standing pool, at the lower end, and deposited in proper vessels, to be drawn out as they were filled."

Lead appears to have been wrought in this county at a very early period. In the neighbourhood of Eggleston, in Teesdale, there are lead mines which have been wrought from the time of Edward VI. Various ancient workings have also been traced here, which, by
the different implements found in them, are supposed to have been wrought by the Romans. The lead mines, as has been already noticed, lie principally in Teesdale and Weardale. The ore is mostly found in veins. Where the adjoining strata consist of limestone, the ore generally produces a considerable quantity of metal; but where the adjoining strata are freestone, indurated argillaceous earth, which are called hence "plate beds," there is little metal in proportion to the ore. Of the different strata of limestone, that which is called "the great limestone," and which is seventy feet thick, has probably produced more ore than all the other strata together. There are generally about eighty-six lead mines worked in this county: Of which, in 1809, four were in Derwent; twenty in Weardale on the north side of the river, fourteen on the south side of the river; and forty-eight in Teesdale. The rent paid to the proprietors is generally one-fifth of the ore. The number of people employed has not been accurately ascertained. Their earnings are about L 40 a-year on an average, each man. Thirty-two cwt. of clean ore generally produces 20 cwt. of lead. The proportion of silver varies much; on the average, 22 ounces are produced from each ton (22 cwt.) in Teesdale. If a ton will not yield 8 ounces, it is not worth working. In Derwent there are four small mills, in Weardale three, and in Teesdale five. In the parish of Middleton, which extends nearly twenty miles from west to east, and between two and three from north to south, nearly the whole of the northern half is one series of lead mines. As the district is very mountainous, the mode of clearing them of water, called hushing, is frequently practiced. These "hushings" frequently raise, and discolor the water of the Tees, destroying its fish in great quantities.

In the western parts of the coal district, great abundance of iron ore is found; and tradition reports, that the Danes wrought it. It certainly appears to have been smelted at some remote period, from the immense heaps of iron slag which are found in various places. They were certainly very regularly and extensively wrought in the middle of the 14th century. In the lead-mining district, a few miles to the north of Stanhope, there is a large quarry, from which grey or freestone millstones, of a very superior quality, are procured. The bed of stone is 21 feet thick; but not more than half of this consists of real millstone. Above it lies a seam of finer freestone. About 40 millstones are sold on an average in the course of the year. What are generally called Newcastle grindstones are got at Gateshead fell in this county. They have been wrought for a great number of years. Some are cut as large as 76 inches in diameter, and 14 or 15 inches thick. A cubic foot of them weighs 1 cwt. 1 qr. 14 lbs. Five thousand chaldrons, each chaldron weighing 14 cwt. are made annually. In times of peace, the greatest demand for them is from Holland and France. Of the various kinds of freestone found in different parts of the county, that found at Heworth is most deserving of notice. It is of an open porous nature, and stands the extreme heat of the glasshouse furnaces better than any other stone or bricks. In the western parts of Durham, grey slate for roofing is abundant. What is called silver sand, and is used in the manufacture of the finer kinds of glass, has been discovered at Seaham.

Limestone. But next to coal and lead, limestone is the most abundant in Durham. The positions and limits of the different limestone districts have already been pointed out. In Weardale, near Frosterley, a limestone is found that takes a fine polish, and the colours are so beautifully variegated, that it is frequently used as marble for chimney-pieces; at Pallison also, several strata of limestone have been lately discovered, which approach still nearer the quality of marble: they are clouded with all the varieties of brown, from a dark brown to a cream colour. This limestone takes a very fine polish, stands any weather, and will not fly with heat; there are four strata of this fine limestone, each three or four inches thick; they lie near the bottom of the quarry; above them is lime of the common quality. For the purposes of agriculture, it has been found that the lime from the quarries to the eastward of the coal district, differ in their effects from the lime brought from the quarries to the westward of this district: the former, when laid on the land in heaps, and suffered to lie some time before it is spread, renders the ground under it unproductive; and hence it is called, "burning lime;" whereas the other lime produces no such effect, and is called "mild lime." These limes have been carefully analyzed by Sir Humphry Davy and other chemists; and the result is, that the limestones to the east of the coal district, that is, the hot or burning lime, contain a large portion of magnesia; and those to the west of the coal districts, called mild lime, are perfectly free from magnesia. The purest of the mild limestone contains 96 of carbonate of lime, and only 4 of residuum; and the worst of the burning lime contains only 44 of carbonate of lime, 42 of carbonate of magnesia, and 14 of residuum. The bad effects on the land were uniformly found to be in proportion to the quantity of magnesia which each contained. According to Mr Marshall, the limestone of Sunderland contains 97 of carbonate of lime. This limestone is of a lightish grey colour; the rock near Sunderland, out of which it is wrought, is upwards of 50 feet high; it is covered with 10 feet of pale clay; there are no regular seams; but it is composed of huge blocks; the interstices are filled with a species of marl.

About thirty years ago, a salt spring was discovered. Salt spring, in an engine pit, constructed for drawing water out of the coal mines near Birtley. As it mixed with the fresh water in the same pit, it would probably have remained unnoticed, but for an accident which happened to the boiler, the bottom of which suddenly dropped. On examining it, it was discovered to be corruded, and encrusted with a large quantity of strong salt. On this the workings were examined, and the springs were found to be confined to a stone drift, that had been driven 200 yards in a north-east direction into the mine. No trace of it is detected any where else, though the pit, and every other near it, have been excavated, both above and below it many fathoms. The depth of the spring is about 150 yards. It is conveyed to the bottom of the pit, whence it is raised by the colliery steam-engine. The spring has never been known to vary, and is as strong now as when first discovered. About 1100 tons of salt are made annually. It produces about 20,000 gallons per day, which is four times stronger than any sea water. At Butterby, near Durham, in the bed of the river Wear, is a spaw, arising from a spring of water, strongly impregnated with salt and sulphur. From the circumstance of its being mixed with the fresh water of the river, it is difficult to ascertain what quantity of salt it holds in solution; but, on several trials, it has produced double the quantity obtained from sea-water. It is much resorted to for its medical qualities. Dore'sdale spaw is sulphureous; it
was discovered, in 1769, in searching for coal. The spring burst forth, with a strong sulphureous smell, at the depth of 24 yards, after boring through red free- stone and whinstone. To the south of Hartlepool is a chalybeate spring, covered every tide by the sea. It is impregnated with a small degree of sulphur;—a gallon yields 120 grains of sediment, in which there appears to be also a considerable portion of lime. In the bed of the river Tees, near Barnard Castle, a sulphu- reous water springs from the crevices of the rocks. It is of the same quality as Harwich water, used for the same diseases, but not so strong.

There are a considerable variety of manufactures in Durham, particularly in the northern part of the coun- try. At Smalwells, anchors of all sizes are made, as well as other kinds of iron work for shipping. At Winlaton Mills, they manufacture files, edge-tools, cane- bills for the West Indies, &c. At this place there is a slitting mill, a mill for grinding edge-tools, and a tilton- forge, which makes 480 strokes in a minute; these are all driven by water. There are several founderies for iron and brass, at Gateshead, near Chester-le-street, at Sunderland, Darlington, &c. On the banks of the Tyne, near Gateshead, and in the vicinity of Sunder- land, great quantities of copperas are made. Formerly salt works at South Shields were very numerous; but latterly their number has much de- creased. There are in the county three works for the manufacture of coppers, one on the Tyne, and two on the Wear. Cotton goods were made till within these few years at Durham; but the manufacture is now laid aside. Darlington is famous for huckaback, diapers, sheetings, &c. which employ 500 looms. Mills for spinning flax were invented here. There are also mills for dressing chamois leather, and for grinding and polishing spectacle glasses. South Shields, Sunder- land, and Stockton are the principal ports in the county; the first has risen into great consequence and wealth within this last half century; since 1740, only four ships belonged to it, amounting to 800 tons; now there are between 40,000 and 50,000 tons of shipping. The number of ships built here annually, on an average, amounts to upwards of 30. Sunderland has also greatly increased in size and commerce. The principal trade, both from this port and South Shields, besides coals, is to the Baltic, and, in time of peace, to Holland. Corn and lead are the principal exports from Stockton.

There are some interesting natural curiosities in the county of Durham. About three miles from Darlington are cavities in the earth, called kall kettles, the ori- gin of which is unknown. Some suppose them to be shafts of old coal works, but this is not likely, as their diameters run from 75 to 114 feet; the depth of the largest is only 19 1/2 feet; and that of the smallest 54 feet. From the probable derivation of the name kall, the ancient British for salt, and kiddle a dam, some imagine them to have been salt pits. About five miles to the north of Hartlepool, is a singular and romantic cluster of rocks, called the Blackhall; some run many yards beyond the light of day; others are open, and supported by natural pillars, which in some places resemble the towers of a cathedral; in other places, the rock is so perforated, as to resemble a fine pointed arch gate- way. Marston rocks, between Shields and Sunderland, are much visited: it is an enormous craggy mass, detached from the coast by the violence of the sea; there is a large opening in the body of the rock, through which boats sail. The quantity of manure left by the sea-fowl which frequent it, is so considerable, as at the expiration of every five or seven years to be generally sold for L.100.

Roman antiquities are not uncommon: near Lanches- ter is one of the most perfect in the kingdom, the Glan- novita of Antoninus' Itinerary; the form is oblong, and it measures 174 paces from north to south, and 160 from east to west, within the walled. At Binchester there is another station, the Vinosium of Antoninus; but it is much less perfect than that at Lanchester.

At the period of the invasion of the Romans, Dur- ham was included in the country of the Brigantes; and on the conquest of Britain, it formed part of the divi- sion, Maxima Cesariensis. In the time of the Saxons, it was part of the kingdom of Northumberland. From the circumstance of its not being mentioned in Domes- day Book, it is supposed at this period to have been in possession of the Scots, or at least in such a disturbed state, as not to be safe for a survey. It is a county palatine, the privileges of which it is supposed to have obtained in the time of St. Cuthbert. Many of the ori- ginal very extensive privileges of the Bishop are now taken away, but he is still in possession of great power. He either acts as lord-lieutenant of the county, or appoints one. The sheriff is appointed by him; he is perpetual chancellor in his territories, all tenures of land originate from him, all estates to which no title can be made escheat to him, and the admiralty jurisdiction belongs to him. Durham sends 4 members to parlia- ment, two for the county and two for the city; but neither were represented till the reign of Charles II. By the returns of the population act in 1811, it appears that the

DURHAM, CITY OF, is in the ward of Easington, 260 miles north from London. Its situation is particu- larly striking and picturesque; indeed a more singular position for the capital of a county can hardly be imag- ined. It is situated on a rocky eminence rising near the centre of the county, and almost surrounded by the rivers Wear, the banks of which here are beautifully and richly fringed with wood. The city descends in steep winding streets to its three bridges, which termi- nate in long suburbs. From all the neighbouring points of view, its appearance is grand and imposing, its public edifices displaying a great degree of magnificence; but when we enter it, much of the grandeur with which it strikes us at a distance is lost; for in general the houses are old, inconvenient, and dirty, and the streets narrow, winding, steep, and extremely incom- modious. The majestic cathedral and stately castle stand on a high circular hill; these, with the streets called the Bailes, are included within the ancient city walls. The situation of the cathedral adds much to its grandeur. The base of the rocks which support its west end, are washed by the Wear; and from the square, called the Palace Green, by which it is general-
Durham.

ly approached, the whole of its north front is at once beheld. It was begun to be built in the year 1095. The centre tower was erected between the years 1233 and 1258. No material additions were made to it since, till the year 1776; at that period great improvements were begun, which are still going on. The cathedral is interesting to architects, as affording "a most instructive series of examples, illustrating the gradual change of style which took place during the reigns of the three first Henries, till by degrees the pointed had completely superseded the semicircular arch; and the heavy clusters of the Norman pillars were polished into the light shafts of the early English." There are several ancient monuments in it; and those of the venerable Bede, Lord Neville, and Bishop Hatfield, are particularly deserving of notice. The Episcopai throne, chapel of 9 altars, library, &c. are also worthy of attention. On the north of the cathedral, there is a large open area, called the Palace Green, on which the castle stands; it is the residence of the Bishop whenever he visits Durham. The views from its upper apartments are singularly commanding, taking in the whole of the city, and the windings of the Wear through a fine county to a considerable distance. It is not known at what period it was built, but probably before the reign of William the Conqueror. The Keep or Tower is the most ancient part; it is an irregular octagon. At present it is a mere shell, but appears originally to have contained four stories besides the vaults: the perpendicular height of the mount on which it stands is 44 feet; round it three pleasant terraces have been formed each 10 feet wide, and communicating with one another. As the buildings which compose the castle were erected at different periods, there is no uniformity of taste or style in them. Out of its north gateway the prison is formed, the anterior accommodations of which have been lately much improved. There are three bridges over the Wear, one of which, called the Bank's Bridge, is rather an elegant structure. Besides these there are six parish churches, exchequer, law courts, college, guildhall, infirmary, &c. From the Palace Green is an avenue that leads to the public walks on the banks of the river; these were made and are kept in repair by the dean and chapter; they accompany the winding of the stream, and command some beautiful views of the city and cathedral. On the one hand, the banks are rocky and abrupt, while on the other they slope gently to the river, covered with wood. "The combination here of trees and buildings, water and rock, home sylvan scenery, and fine distances, is at once beautiful and grand."

Durham sends two members to parliament. The right of election is vested in the corporation and freemen, who at present amount to about 1200: the city is governed by a mayor, twelve aldermen, twenty-four common-councilmen, recorder, town-clerk, &c. It is deemed one of the best bishoprics in England; and the livings in the bishop's gift, the richest. The present endowment for a deanship was established by Henry VIII. with twelve prebendaries, twelve minor canons, &c. During the protectorate of Oliver Cromwell, an attempt was made to establish an university here, but it was suppressed at the restoration, and the buildings, which are still called the college, were given to the dean.

The manufactures consist of woollen goods, such as shallows, tamnies, carpets, &c. The neighbourhood of the city is famed for large crops of mustard, which pay remarkably well, Durham mustard being in great request all over the kingdom. At the end of March there is a fair, which lasts for three days, principally for cattle, sheep, and horses; there are also fairs on Whit-Tuesday, and on the 16th of September. Saturday is the market day. The population in 1811 was 6763. See Hutchin's History of Durham; Warner's Northern Tour; Granger's Account of the Agriculture of Durham; Bailey's Agriculture of Durham; Marshall's Review of the Agricultural Reports from the Northern Department of England; and Beauties of England and Wales, vol. v. (w. s.)

DURIOA, a genus of plants of the class Hexandria, and order Monogynia. See Botany, p. 184.

DURSLEY, a town of England in Gloucestershire, is situated at the base of a steep hill, clothed with a fine hanging wood of beech trees. The town, which isirregularly built, consists of two narrow streets, crossing each other nearly in the shape of the letter T. The principal public edifice is the church of St James's, which is a large and elegant building. It consists of a spacious nave, side aisles, and a chancel, with a modern Gothic tower at the west end, and an elegant portal on the south. The old spire fell in 1699, during the ringing of the bells, and several persons lost their lives. In 1700, it was rebuilt at the expense of L.1000. The market house, which stands near the centre of the town, was built in 1738, and is wholly of free-stone. At the east end of it there is a statue of Queen Anne. "On the south-east side of the church-yard," says Mr Rudge, "some springs arise out of the ground like boiling water, in so copious a manner, as to drive a fulling mill at about a hundred yards distance below, and are never known to diminish in quantity. At their rise they cover a fine level gravelly bottom for about 15 feet square."

The cloth manufacture is carried on here to a great extent, by means of machinery, and cards are also manufactured for the clothiers. There is an extensive paper manufactory adjacent to the town. There is found in the neighbourhood a peculiar kind of stone, without any chip or slit, called trowe stone, which is at first soft, and afterwards indurates by exposure to the air.

The following is the abstract of the population return for the parish in 1811.

| Inhabited houses | 489 |
| Families that occupy them | 561 |
| Families employed in agriculture | 68 |
| Do. in trade and manufactures | 365 |
| Males | 1151 |
| Females | 1429 |
| Total population | 2580 |

DUSKY BAY. See Zealand New.

DUSSELDORF, a town of Germany, and recently the capital of the grand duchy of Cleves and Berg, is situated on the Rhine near its confluence with the river Dussel. The streets are regular, clean, and spacious, the houses lofty, and the public buildings numerous and handsome. The principal objects of curiosity, are the hotel de ville, the equestrian statue of John William, Elector Palatine, by Grippelo; the hotel of the former government; the barracks, which were built by the Elector John William, and held eight battalions, each of which has its particular church; the collegiate church, containing a marble monument of the Duke John; the cideon church of the Jesuits, which is the
At the distance of about half a league from the town stands the convent of La Trappe, where the religious manufacture and sell snuff-boxes with cyphers, which are held in high estimation. Cromford and its manufactories, the fine view from the summit of the Grafenberg, and the cavern in the mountain of Klutter, are also worthy of being seen. At the distance of 4½ miles from Dusseldorf are the baths of Schwelm, which are much frequented in summer. The population of the town is 12,000.

SECTION I.

**History of Dyeing.**

5. **The perception of colour seems to be accompanied with immediate pleasure; and though the effect is probably heightened by association, it is so instantaneously produced, that we are only conscious of the pleasing emotion, and seldom think of searching beyond it for the source of our delight. Long before we are capable of analyzing our feelings, the eye is caught with the brilliancy of colour, and the splendour of illumination. Even the lower animals are not altogether insensible to the beauties of rich and variegated tints; and man in his rudest state, has always regarded colour as a principal constituent of ornament. Nor is it only in the judgment of the infant or the savage that colours rank high among the elements of beauty; in the most refined periods of human society, they retain an undiminished attraction, or rather acquire a more powerful influence by the cultivation of taste.** Among the several kinds of beauty," says Mr. Addison, "the eye takes most delight in colours. We no where meet with a more glorious or pleasing show in nature, than what appears in the heavens at the rising and setting of the sun, which is wholly made up of those different stains of light, that show themselves in clouds of a different situation. For this reason we
find the poets, who are always addressing themselves to the imagination, borrowing more of their epithets from colours, than from any other topic."—Spect. No. 412.

6. To this delight which we derive from the perception of colour, must be referred the origin of dyeing. The savage would naturally wish to recall the pleasure which he experienced from viewing the varied and delicate tints of the vegetable world, by transferring their colouring principles to objects less fleeting in their nature, and more frequently present to his sight. His first efforts would be rude and imperfect; and might consist in rubbing his body with the expressed juices of fruits and flowers, or in communicating a fugacious tinge to his simple articles of dress. His fondness for brilliancy and variety, would prompt him to make trial of different substances; and though many of his experiments, as they were guided by no fixed principle, might fail, some of them would succeed, and thus gradually lead to the discovery of useful dyes. Perseverance would supply the place of knowledge, and accident would sometimes disclose what ingenuity might never have found out. These remarks may even be applied to dyeing, after the art had attained a more advanced state, and when it might have been expected that science would have lent greater assistance to a subject so susceptible of being improved by inductive investigation. It has often been regretted, however, and not without reason, that almost every important discovery in the arts has been the offspring of accident, and that science has done little more than suggest some hints for improving what chance may have offered to human observation.

7. The origin of dyeing must, therefore, be referred to a period far beyond the records of authentic history. The art appears to have been cultivated by the Egyptians from the earliest times; but it is extremely probable that it passed to that people from the Hindoos and other inhabitants of India, who seem to have practised dyeing at a still more remote period. Indeed, almost all the arts and sciences have originated in that quarter of the globe; and though, on account of the political and religious institutions of the East, they never attained there any great degree of perfection, they gradually spread among other nations less fettered by prejudice, and more disposed to adopt whatever might be regarded as improvement. It is remarked by Major Renne, "that a passion for Indian manufactures and products has actuated the people of every age, in Lower Asia, as well as in the civilized parts of Europe: the delicate and unrivalled, as well as the coarser and more useful fabrics of cotton of that country, particularly suiting the inhabitants along the Mediterranean and Euxine seas. To this trade, the Persian and Arabian gulf opened an easy passage; the latter particularly, as the land carriage between the Red Sea and the Nile, and between the Red Sea and the Mediterranean, took up only a few days. It is highly probable, continues he, and tradition in India warrants the belief of it, that there was, from time immemorial, an intercourse between Egypt and Hindostan, at least the maritime part of it; similarity of customs in many instances, as related of the ancient Egyptians by Herodotus, (and which can hardly be referred to physical causes,) existing in the two countries."

8. The natural fertility of India, and the great variety of materials which it affords for cultivating the art of dyeing, were extremely favourable to its improvement. But religious prejudices, and the unalterable division in to 'east," soon imposed restraints upon industry; the arts became stationary; and it would seem that the knowledge of dyeing cotton was as far advanced when Alexander the Great invaded the country, as it is at present. Even at this day, the Indian processes are so complicated, tedious, and imperfect, that they would be impracticable in any other country, on account of the price of labour. European industry has far surpassed them in correctness of design, variety of shade, and facility of execution; and if we are inferior to them with respect to the liveliness of two or three colours, it is solely to be ascribed to the superior quality of some of their dyes, or perhaps to the length and multiplicity of their operations.—See Berthollet.

9. The Egyptians do not seem to have made any important additions to the knowledge of dyeing, which they borrowed from their eastern neighbours; and indeed little could be expected from the genius or industry of a people who were strictly prohibited by the principles of their religion, from changing even their most indifferent customs. It appears, however, according to Pliny, that they were acquainted with a mode of dyeing, very much resembling calico-printing. He mentions that the Egyptians began by painting on white cloths, with certain drugs, which in themselves possessed no colour, but had the property of abstracting or absorbing colouring matters; that these cloths were afterwards immersed in a heated dyeing liquor, of a uniform colour, and yet when removed from it soon after, that they were found to be stained with indelible colours, differing from one another according to the nature of the drugs which had been previously applied to different parts of the stuff.—See Plin. lib. xxxv. cap. ii.

10. From Egypt, the knowledge of dyeing seems to have been communicated to the inhabitants of Tyrus, to whom the art became indebted for the discovery of one of the most celebrated dyes known to the ancients. This species of dye, called the Tyrian purple, which was subsequently either lost or neglected, soon became an object of the most refined luxury, and contributed greatly to the opulence of that enterprising and industrious people. The circumstances which led to the discovery of it are very imperfectly known: but fiction has supplied the want of historical facts, and described its origin with sufficient minuteness of detail. According to one account, the merit of its discovery is due to a dog belonging to a certain Hercules. We are informed, that when this dog was accompanying his master along the sea-shore, who was then following the nymph Tyros, the animal seized one of the purpurae lying on the sand, and breaking the shell with its teeth, his mouth soon became coloured with the purple juice. The nymph having observed the effect, immediately expressed a strong desire to obtain a dress dyed of the same beautiful colour; and her lover, no less anxious to gratify her wishes, at last succeeded in discovering a method of applying it to cloth. The name of the nymph by whom the colour was first worn being Tyros, the dye itself was called the Tyrian purple.—See Cassiodorus, lib. 1.; Jutius Pollo, lib. 1. 4.

11. Others ascribe the discovery to the Phœnician Hercules, and affirm, that he afterwards communicated it to the King of Phæacia, who immediately after began to wear purple, and was so jealous of its beauty, that he forbade the use of it to his subjects, reserving it exclusively for the robes of royalty. It is probable, however, that this colour was first discovered at Tyre,
and on that account received the name of Tyrian purple; more particularly, as the epithet Sarraus, from Sarras, the ancient name of Tyre, was frequently applied to it.

12. The more ancient writers differ no less with respect to the time when the Tyrian purple was discovered, than with respect to the circumstances which led to its discovery; some stating it to have been 1500 years before the commencement of the Christian era, and others nearly a century later, at the time Minos reigned in Crete. Frequent mention is made of purple in the books of Moses; but whether the colour alluded to was the Tyrian purple, or communicated by a different process, is difficult to determine. At any rate, the frequency (Exod. xxv. 6; xxvi. 1.) with which it is mentioned, implies that some method of dyeing purple was common among the Israelites soon after they settled Egypt, which was nearly about the period already stated (1401 B.C.) The great antiquity of this colour is also confirmed by the testimony of Homer, who represents his heroes to have been dressed in purple.

13. This colour was so highly valued by the ancients, that it was either consecrated to the worship of the Deity, or conceived to be fit only for the garments of royalty. Under the Mosaic dispensation, the stuffs for the service of the altar, and the habits of the high priests, were enjoined to be of purple. The Babylonians devoted this colour to the dress of their idols, and most of the other nations of antiquity seem to have done the same thing. Pliny informs us, that it was used by Romulus, and by succeeding kings of Rome, as well as by the consuls, and first magistrates under the republic. The Roman emperors at last appropriated it entirely to their own use, and denounced the punishments of death against those who should dare to wear it, though covered with another colour. This absurd and tyrannical restriction confined the dyeing of the Tyrian purple to a few individuals; and in a short time the knowledge of the process was completely lost. In the twelfth century, neither the shell fish which furnished the dye, nor the methods which the ancients employed to communicate to cloths the rich and beautiful purple which it afforded, were at all known; and on the revival of learning, it was even suspected by many, that the accounts which have come down to us respecting this celebrated colour, were entirely fabulous.

14. Notwithstanding the very high esteem in which the Tyrian purple was held by the ancients, and the great encomiums which have been bestowed on it by many of the moderns, the loss of it is perhaps scarcely an object of regret. The shell fish which furnished the purple dye probably exist now, says Berthollet, in as great abundance as formerly. They have been so accurately described, that they may be recognized; and, in fact, Thomas Gage informs us, that shell fish have been found near Niceya, a small Spanish town in South America, which possess all the properties described by Pliny, and other ancient writers. These shell-fish, it appears, are at present used in dyeing cotton on the coasts of Gungaquiil and Guatimala. Cole, in the year 1669, discovered some of them on the English coast, and Plumier found a species of them at the Antilles. Reaumur has made many experiments on the wholes which he obtained from the coasts of Poitou, and Duhamel has minutely examined the colouring liquor of the purple shell fish which he found in great abundance on the coast of Provence. He observed that this liquor does not take a purple colour without the action of light, a circumstance which Reaumur had before remarked respecting that of the whelk; that though at first white, it becomes of a yellowish green, which deepens to a sort of blue; that it afterwards reddens, and in less than five minutes becomes of a very fine deep purple. In all these respects, the colour produced possessed the characters of the ancient purple. If this method, therefore, of dyeing purple is no longer practised, it is not on account of our ignorance of the process, but because we are acquainted with more beautiful, as well as much less expensive dyes; though, as Dr Bancroft remarks, the purple afforded by the shell-fish in question, may still be applied with advantage in topical dyeing, for which but little colouring matter is required.

15. The art of dyeing seems to have made but little progress among the Greeks; a fact which must undoubtedly be ascribed to the little estimation in which the arts that contribute to convenience or luxury were held by that warlike and high-minded people. Public opinion placed the fine and the useful arts at an immense distance from each other; for while the highest glory was connected with the former, the latter were degraded among the dishonourable and servile employments. Accordingly we find, that though the more opulent inhabitants of Athens preferred coloured clothes, the dress of the common people was made of cloth which had received no dye. The art of dyeing linen appears to have been unknown in Greece before Alexander the Great invaded India; where, according to Pliny, his captains, in skirmishing on the banks of the Indus, first saw, to their astonishment, the enemy changing the ensigns of their vessels, and suddenly displaying others of different colours. Even the dyeing of woollen stuffs seems to have made little progress at that time, as the same author, after declaiming against the luxury of his contemporaries for wearing clothes dyed of colours which rivalled those of the finest natural flowers, observes, that none of these flower colours were in use during the time of Alexander. It is probable, however, that the companions of that conqueror brought back from Persia and India some information respecting the rich dyes employed in those countries, which they afterwards diffused among their countrymen.

16. The Romans borrowed almost all the knowledge of dyeing which they possessed from the Greeks, together with the same contemptuous notions with regard to the art. The sentiments of the Greeks and Romans in this respect, afford a remarkable contrast to the more liberal and enlightened views of the present day, and furnish one of the most striking characters by which the philosophy of the ancients is distinguished from that of the moderns. The ancients appear to have undervalued everything that contributed to domestic comfort and enjoyment; and while they professed the most enthusiastic regard for the public good, to have forgotten that the grand aim of all patriotism ought to be the promotion of individual happiness. They accordingly degraded the useful employments, and reserved their esteem for arts whose productions could seldom be brought in contact with ordinary affairs. The moderns, less actuated by
DYEING.

17. Next to the Tyrian purple, the Romans valued most highly the colour obtained from the kermes, or coccius ilicis. Pliny mentions that this dye was sometimes employed with the colour of murex and buceinum, (the shell-fish which gave the Tyrian purple) in producing a sort of purplish crimson, called by the Romans hygginum. He states, that this substance was brought from Galatia, or from the neighbourhood of Emerita in Portugal, and that the latter was reckoned most valuable. We learn also from Pliny, that the kermes, like the Tyrian dye, was at last appropriated for dyeing the imperial robes, though it must have yielded a colour greatly inferior to that which is obtained from it at present, as he insinuates that it was not durable. This last circumstance would lead us to suspect, that at that time the ancients were unacquainted with the use of alum as a mordant, though such an opinion is rather discon- nected from other facts stated by Pliny. In his 35th book, chap. xv. De Sulphure, Alumine, et gencrichus corum, §c. he describes several species of alum; that of these the island of Cyprus afforded two, one white, and the other black; and that though their colours differed but little, their uses were extremely different. The white alum, he adds, is principally used for dyeing wool with clear and bright colours; the black, for dyeing brown and dark colours. He afterwards notices five different kinds, and concludes with observing, that all the different kinds of alum were possessed of an astringent property. Beckmann has endeavoured to prove that the alum of the ancients was totally different from the triple compound to which the moderns apply the term alum, and consisted in a combination of sulphuric acid, with either iron or copper, or perhaps zinc, formerly known by the names of green, blue, and white vitriols. In support of his opinion, he mentions that the Greek and Roman writers mention only native alum, a salt of very rare occurrence; while no account is given of any Work for its artificial preparation, except one in Spain, noticed by Pliny, which was intended to crystallize the sulphates of copper or iron. But the passage already referred to, renders it extremely probable that the common sulphate of alumine was included among the substances to which he gave the appellation of alumum; though it is no less certain, that the sulphates of iron and copper were classed along with it, as he expressly states that two of them produced a black colour, with galls, and the peels of the pomegranate.

18. Besides the Tyrian purple, and the various shades of red from the kermes, the Romans were acquainted with several other colours. It was customary among them, from the earliest times, for newly married women to wear a yellow veil, a colour which was confined entirely to matrons; and those who were employed in the games of the circus were distributed into divisions, each of which was dressed in an appropriate colour. The colours mentioned are color prassius, green; rusfus, orange; venetus, grey, or perhaps a light blue; and white. Some idea may be formed of the qualities of these colours, by enumerating the substances with which they were procured. It is difficult to give a complete account of them; but the following seem to have been the most important: madder, woad, the roots of anehusa tinctoria, or alkanet; the genista tinctoria, or dyer's brome; gallnuts, pomegranate peels, elder bark, the rinds of walnuts, the bark of the walnut tree, and the pods of the Egyptian acacia. No account, however, has been transmitted to us, either by Greek or Roman writers, respecting the methods in which these substances were employed, or of the mordants that were used along with them to give fixity to their colouring principles.

19. The ancients were ignorant of the use of soap, a substance which gives the moderns a decided superiority over them in preparing the stuff for the reception of the dye. In order to remove the grease from the wool, and wash linens, they employed a plant called by Pliny radix—

cula, and by the Greeks εργελον, supposed to be our sa- pounaria, or soap-wort. Pliny notices another plant which was used for the same purpose. Homer represents the Princess Nausicaa and her attendants washing their linen clothes in the ditches, by trampling on them with their feet.

20. Whatever knowledge of dyeing the ancients possessed, appears to have been lost about the fifth century, a period when almost all the arts were forgotten, and scarce any traces of civilization remained in the western empire. A faint knowledge of the arts was, indeed, retained in Italy, and kept alive by occasional intercourse with the East, in consequence of the crusades; and also by the importation of various articles of luxury and refinement, which was made at that time by the Venetians from the same quarter. This importation continually afforded new materials for industry, and new objects for imitation, and gradually led to the revival of the arts in Italy. The knowledge of the methods of dyeing, as practised by the Greeks and Romans, was in some measure restored by the acquisition of chemical science, which now began to shed a feeble light over the objects of human industry, and attained a state of improvement probably not inferior to that in which it existed in ancient times.

21. From Italy, the knowledge of dyeing gradually spread itself through the other states of Europe. Archil is said to have been discovered at Florence about the year 1300, by a merchant of that city, who hap-
pening to observe that urine imparted a very fine colour to a certain species of moss, was induced to make experiments upon it, and thus learned the preparation of archil. In the year 1429, a treatise on dyeing made its appearance at Venice, of which an improved edition was afterwards published in 1510. This work, however, was very imperfect; and in order to render it more useful and extensive, Giovann Ventura Rosetti, overseer of the arsenal at Venice, resolved to travel through the different parts of Italy, and the neighbouring countries, where dyeing was practised, to obtain an accurate acquaintance with the various processes of the art, and reduce them under a systematic form. He accordingly carried his design into effect, and in 1548, published the result of his observations and enquiries under the assumed name of Pistola. This work united the different processes then employed, and, in the opinion of Bischoff, ought to be regarded as an important step towards the perfection which the art of dyeing afterwards attained, though, according to Hollar, it is but little entitled to attention. It is a curious fact, that it contains no account either of cochineal or indigo. Bischoff explains this circumstance, by supposing that neither of these dyes was employed at that time in Italy. Whatever uncertainty may exist with respect to the time when cochineal was first used as a dye, no doubt can be entertained, that long before the period at which Rosetti published his work, the properties of indigo were well known. Bischoff indeed conjectures, that the indicum of Pliny was not a dyeing drug, but a substance used as a paint, and very different from our indigo; and that the contract which was made in 1194, between the cities of Bologna and Ferrara, respecting certain duties to be levied at the former upon indigo, had a reference to the indicum of Pliny. Dr Bancroft, (Philosophy of Permanent Colours, vol. i. 242,) however, has shewn the identity of these substances, from the exact coincidence of the properties of indicum, as described by Pliny, with those of the modern indigo; and he quotes a passage from Caneparius, which proves that indigo was brought by merchants from India and Alexandria, and thence imported to Venice, when that city was the entrepot of Europe and the East. The statement of Caneparius also seems to correct a mistake committed by Berthollet, who mentions that the first indigo employed in Europe was imported by the Dutch from the East Indies. The fact is, that long before the Dutch had any intercourse with that country, indigo had been imported in considerable quantity from Egypt and Syria to Italy, and employed in dyeing. Bischoff also has established, by the most decisive evidence, that indigo was employed as a dye before the Dutch visited the East Indies. He informs us, that woad-dyers were recognized among the Germans as a distinct trade, so early as 1329, and that they were afterwards incorporated by charter with certain dyers from Italy and Flanders, under the name of Art, Woad, and Fine Dyers; that this body, soon after its establishment, excelled the jealousy of a more ancient corporation, the Black Dyers; and as indigo was employed by the former, the Black Dyers exerted themselves so successfully in depriving the use of it, that the Elector of Saxony, listening to their selfish suggestions, was prevailed upon to issue severe prohibitions against those who should employ it in dyeing. In the prohibitory edicts which were passed against it, it is described as a corrosive colour, and fit food only for the devil. These acts were passed between the years 1521 and 1547, which was a considerable time before the first voyage undertaken by the Dutch to the East Indies. See Indigo.

23. Though the knowledge of dyeing had now extended itself over the more civilized parts of Europe, the principles of the art seem to have been still in a great measure confined to Italy and Venice; a circumstance which contributed, in no small degree, to the prosperity of these states. Accident, however, has frequently led the way to important discoveries, and in some cases contributed more to the improvement of the arts, than the most refined speculation guided by experience. This remark is peculiarly applicable to the discovery of scarlet, one of the most brilliant colours known in dyeing. "The etymology of the term scarlet is involved in some obscurity. Ptolemy thought it of Celtic origin, and that it signified Galatian rubor. (See Antiq. Celt. p. 69.) But according to Beckmann, Silber asserts that scarlet is a German word, compounded of schor, fire, and lacken, cloth; while Rerske, on the contrary, derives the word in question from the Arabic scarab, meaning the kermes dye. See Bancroft.

23. Whatever be the origin of the term, the colour to which it was applied seems to have been known at a very early period. Beckmann quotes a passage from the Historia Celtrica Pontani, in which it is affirmed, that Henry III. of France conferred upon the Count of Cleves the Burgervaste of Nimeggen, on condition of his delivering to him annually three pieces of scarlet cloth, manufactured from English wool, (tres pannos scarlaticinos Anglo- nan.) The same author also refers to a work published in 1211, entitled, "Gervasiil Tiberiiensis obsi Imperialia at Ottomum IV. Imperatorem," from which he quotes the following observation applied to the kermes: "Vermiculus hic est, quo tincturum pretiosissimus regnum panni, sive serici, ut exami, sive lanae, ut scarlata."

The colour, however, to which the term that gave rise to our word scarlet, was then applied, was very different from the colour which now bears that name; the former having been obtained from the kermes, whereas the latter is procured from cochineal, and excited in brilliancy by the application of a particular mordant. The insect to which we give the name of cochineal was unknown in Europe before the discovery of America. When the Spaniards first visited Mexico about the year 1518, they observed that the native inhabitants of the country employed cochineal for communicating a colour to some parts of their domestic utensils, ornaments, &c. and also as a dye for cotton. They were so struck with its beauty, that an account of it was transmitted to the Spanish ministry; who accordingly, in the year 1523, ordered Cortes to adopt proper measures for increasing the produce of a commodity which appeared to be of the utmost value as a dye. The Mexicans are said to have employed cochineal as a dye long before they were visited by

* This is proved by the following passage from Caneparius, "Iaties est herba, que ante fiorum colligitur et sub mola tunditur, et facto ex ipa cumulo maceratur soli, mov in magnos globos redacta, et sub tecto locata aspergitur aqua, ut magis, potiusque maceratur, tunc edidit magnum fictorem et nigrescit, et sic preparatis iaties sit glisti diecutur idem est, percutitur ad finituras."—"The supposed of Caneparius," says Dr Bancroft, "that indigo was obtained from the iaties, or wood plant, seems to have been prevalent in this country, so late as 1640."
DYEING.

Money, and to have used an aluminous mordant to give it fixity. It appears even that for a considerable time after the introduction of the cochineal into Europe, this was the only mordant employed in dyeing with it; so that the only colour obtained from cochineal at first must have been a crimson, which we learn indeed was the case, on the testimony of Cancarini (De Altramentibus, p. 191.) About the year 1630, it was accidentally discovered that the nitrate of tin possessed the property of exalting, in a very eminent degree, the colour of this drug, and converting it from a dull crimson to an intense and brilliant scarlet. Kanneal and some others inform us, that a German chemist, of the name of Kuster or Kuffer, having accidentally dropped a solution of tin by aquafortis into a decoction of cochineal, was the first who observed the singular effect; while Beckmann asserts, that we owe the discovery of scarlet to a Dutch chemist of the name of Cornelius Drebbel, who was born at Alkmaar, and died at London in 1634; and that Drebbel communicated the discovery to Kuffer, who was then an eminent dyer at Leyden, and afterwards became the son-in-law of Drebbel. Beckmann also states, that Kuffer soon after took advantage of the discovery, and reduced it to practice in his dye-house; and that the scarlet thus obtained was at first named Kuffer’s colour, and afterwards Dutch scarlet. A Flemish painter of the name of Kloock or Ghiek got possession of the secret, either directly from Kuffer himself, or by means of some hints which he had obtained concerning the process employed by the latter. Ghiek communicated the information which he thus procured to the famous Gobelins at Paris; and another Fleming, named Kepler, carried the secret to England about the year 1643. A dye-house was soon after established at Bow, near London, and hence the new scarlet was for some years called the Bow dye. See Baneroff, vol. i. p. 448.

24. About the year 1662, the Royal Society of London, then recently established, directed their attention to dyeing; and in order to promote the improvement of the art, desired Dr Haak to prepare a translation of the work, entitled, Phleths, which, as we have already stated, had been published about a century before in Italy. This translation, however, was never executed; but at that time Sir William Petty, in consequence of a request from the Society, laid before them “An Apparatus to the History of the common practice of Dyeing,” which afterwards appeared in Dr Spratt’s History of the Royal Society, and is perhaps the first original treatise on dyeing which has appeared in our language. Soon after, Mr Boyle gave an account to the Society of his experiments on colours; and towards the conclusion of 1664, the Society enjoined that “the way of fixing colours should be recommended to Mr Howard, Mr Boyle, and Dr Meritt.” This recommendation does not appear to have been productive of any useful discovery in dyeing, or even of any improvement of its processes; but it served to turn the attention of other members to the subject, and on the 11th of November 1669, “Mr Hook,” who was always distinguished by the ingenuity and originality of his views, “produced a piece of calico stained after the way contrived by himself, which he was desired to prosecute on other colours besides those that appeared in this piece.” (Birch, Hist. Roy. Soc. vol. ii. 401.) And accordingly, on the 9th of the following month, “he produced another specimen of staining with yellow, red, green, blue, and purple colours, which he said would endure washing with warm water and soap.” It was not to be expected, however, that, in the very imperfect state of chemical science at that time, a few random experiments could give much information to practical dyers, who had better opportunities of observing the result of fortuitous mixtures, and were equally well prepared to take advantage of whatever accident might present to their notice. We accordingly find, that for nearly a century afterwards, no important improvement in dyeing was suggested by men of science in this country.

25. In France, industry, which had languished during the administration of Richelieu and Mazarin, was revived by the fostering care of Colbert, and raised to a high pitch of pre-eminence among that of the other nations of Europe. That enlightened statesman, among other objects of his care, turned his attention to the improvement of dyeing. He invited the most skilful artists to settle in France, and afforded every encouragement to the establishment of manufactories in various parts of the country. In order to correct, as well as to prevent the frauds which were practised by dyers, he published, with the assistance of M. D’Albo, a set of regulations in 1669, and afterward in 1672, under the title of Instruction generale et pour la teinture des laines et manufactures des laines de toutes nuances, et pour la culture des drogues qu’on y emploie. This legislator first endeavours to show that dyeing is an object deserving public attention, from the additional value which it confers upon many of the articles of commerce. “If the manufactories of silk, wool, and thread, are to be reckoned among those which most contribute to the support of commerce; dyeing,” says Colbert, “which gives them that striking variety of colour, by which they resemble what is most beautiful in nature, may be considered as the soul of them, without which the body could scarcely exist. Wool and silk, the natural colour of which rather indicates the rudeness of former ages, than the genius and improvement of the present, would be in no great request, if the art of dyeing did not furnish attractions which recommend them even to the most barbarous nations. All visible objects are distinguished and recommended by colours; but, for the purposes of commerce, it is not only necessary that they should be beautiful, but that they should be good, and that their duration should equal that of the materials which they adorn.” The regulations of Colbert were intended, however, rather as restrictions to control, than as directions to instruct the dyers in the management of their operations. They admitted the former division of dyers “en grand,” who were confined to colours deemed permanent, and dyers “en petit teint,” who were permitted to dye only such as were fugitive; while they particularly specified the different substances which both were to employ in their respective processes. These restrictions, which were imposed chiefly with the view of guarding the public against imposition, would have been productive of still greater evils than those they were intended to obviate, had they not been easily eluded, and had not the government at the same time held out the promise of rewards to those whose experiments contributed to the progress of the art.

26. During the administration of M. D’Oray, the Theoretical opinion of Dufay.
DYEING.

for the improvement of the art. Dufty, who was committed in drawing up this act, appears to have been the first who entertained just notions concerning the cause of the attraction of colouring matters to stuffs, particularly in those cases in which an immediate affinity subsists between them. Without this affinity, he stated, that the cloth in a dyeing bath would never acquire an intensity of colour greater than that of the liquor in which it was immersed, but share the colouring particles, by a mechanical division, equally between itself and the bath; a state of things which is by no means conformable with experience, as the stuff sometimes attracts all the colouring matter, and leaves the liquor in which it was dissolved perfectly limpid. "This seems to indicate," says Dufty, "that the ingredients have little attraction for the water than for the particles of the wool." He also observed the different degrees of attraction which different substances, as wool and cotton, exert upon colouring matters; but he appears to have had no just opinion concerning the operation of mordants, or those substances which are sometimes necessary to connect the colour with the stuff. His successor Hellot published an excellent practical treatise on the methods of dyeing wool; but all his theoretical notions were led astray by a very absurd hypothesis, which he seems to have adopted without the smallest proof. In all the processes of dyeing, he conceived that a sulphate of potash was formed; and that this salt, being sparingly soluble in cold water, and little affected by air or light, first diluted the pores of the stuff to be dyed, thus preparing it for the reception of the colouring particles, and afterwards wedged these particles so closely together, that it became impossible for them to make their escape. This hypothesis, which was neither supported by fact, nor countenanced by sound reasoning, was admitted without proof, and regarded for a considerable length of time as a true explanation of the cause of the adhesion of the colouring matter to the stuff. "I believe," says he, "it may be laid down as a general principle in the art of which I am now treating, that all the invisible mechanism of dyeing consists in dilating the pores of the body to be dyed, in depositing in them particles of foreign matters, and retaining them there by a kind of covering not liable to be effected by water, rain, or the rays of the sun; in choosing colouring particles of such a degree of fineness as to be rendered sufficiently fixed in the pores of the stuff opened by the heat of boiling water, and again constricted by cold, and also coated by the kind of varnish which the salts employed in its preparation had left in those pores; whence it follows, that the pores of the fibres of the wool which has been wrought, or is to be wrought into cloth, should be cleansed, enlarged, coated over, and then constricted, so that the colouring particles may be retained in the pores nearly in the same manner as the diamond is retained in the collet of a ring." Notwithstanding the erroneous views of Hellot, the inferences which he deduced from them were not destitute of practical utility, and many of the processes which he recommended may be followed with the same advantage as if they had been derived from more scientific principles. Nor shall we wonder at this, if we reflect that the most correct theory seldom does more than illustrate the nature of the practical operation which experience has previously discovered to be useful.

Opinions of Hel lot.

Opinions of Macquer.

27. The theoretical opinions of Hellot were adopted by the celebrated Macquer, whom the French government had appointed his successor for superintending the practice of dyeing; and cultivating such branches of science as had a tendency to promote the improvement of the art. In a memoir which is printed among those of the Royal Academy of Sciences for 1749, he not only admits the justness of Hellot's views; but expresses a high admiration of the ingenuity of his theory. "Ce savant chimiste est le premier qui ait porté le flameau de la physique dans l'art obscure de la teinture, et qui ait rassemblé et mis en ordre, suivant les principes d'une théorie ingenieu se, les phénomènes et les opérations bizarres de cet art: il a mis les chimistes à porté de voir, clair dans ce chaos ténèbres. Macquer seems to have held the same sentiments concerning this very absurd hypothesis, so lately as the year 1766; for, in the eulogy pronounced by him on Hellot, and inserted in the Memoirs of the Academy for that year, he expresses himself thus strongly, a l'aide de cette théorie si lumineuse, on ne sera plus trompé dans la pratique de cet art, que lors qu'on vendra bien l'être. Some allowance, indeed, must be made for that studied determination to praise, which characterizes too many of these eulogies.

28. The labours of Macquer, however, contributed greatly to improve and extend the practical operations of dyeing, particularly of dyeing silk, to which he devoted much of his attention. He was the first who ascertained the real nature of Prussian blue, and he endeavoured to make an application of his discovery to the purposes of dyeing. He intended to have published a complete dissertation on the art, and in 1781 actually drew up a prospectus of the work; but a continued state of bad health prevented him from prosecuting his design, and he died in 1784 without having accomplished his intentions. Before his death, he abandoned the hypothetical opinions of Hellot, and embraced the more rational theory of the processes of dyeing which, before that event, had been suggested by Keir, and demonstrated by Bergman and Berthollet.

29. Mr Keir, the ingenious translator of Macquer's Chemical Dictionary, appears, according to Mr Henry, to have been the first who proposed a true explanation of the cause of the adhesion of the colouring matters to stuffs. He suspected that when the aluminous mordant was employed, the earth of alum was precipitated, and in this state became attached to the cloth; an opinion which, as we have already hinted, was latterly adopted by Macquer himself, and enforced at the article Teinture of his Dictionnaire de Chimie. Berthollet, on the other hand, ascribes the true theory of mordants, by whom first suggested.

Opinions of Bergman.

Opinions of Macquer.

20. We are indebted to Bergman, however, and more

Benefits which he conferred upon dyeing.

True theory of mordants, by whom first suggested.
particularly to Berthollet, for the complete demonstration of the truth of these opinions. The latter of these celebrated chemists succeeded Macquer in the place of trust which he held in France under the commercial department of administration, and by conjoining extensive observation with enlightened theory, has done more than any of his predecessors to promote the improvement of dyeing, and to raise it from an obscure empirical art, to the rank of a branch of chemical science. Since his appointment to the superintendence of the arts connected with chemistry, almost all the investigations which he has inserted in the 

**Memoirs of the Academy, in the Journal de Physique, and the Annales de Chimie,** relate more or less to the elucidation of the arts. In 1791, he published his *Elements of the Art of Dyeing,* in 2 vols. 8vo, a second edition of which, with considerable improvements, appeared in 1803. This treatise may be regarded as a standard work on dyeing, since it contains not only a detailed account of the practical operations of the art, but a theoretical view of the principles upon which they are founded. The subject of dyeing has also attracted the attention of Chaptal, who held, for a considerable time, the office of minister of the interior, under the French government. This excellent chemist, in his work entitled, *Chymie appliquée aux arts,* has introduced many original observations on dyeing, and described the leading processes of the art with much philosophical elegance. He investigated, with great care, the nature of Adrianople red, and published the result of his experiments and observations on that celebrated colour, in the 26th vol. of the *Annales de Chimie.* Several other chemists in France have written dissertations on dyeing, which deserve to be noticed in this place. Among these we may mention a small but useful work by M. Vitalis de Rouen, entitled *Manuel de Teinturier sur fil et sur coton filé,* a French translation of Scheffer, which first appeared in 1748, and was reprinted with notes by Bergman; another of Penner from the German; and an original work by Dambournay. The treatise of Scheffer was chiefly intended for the benefit of Swedish dyers; that of Penner contains an account of many experiments made by the author to ascertain the qualities of different dyes, but these seem to have been guided by no scientific views; and the work of Dambournay is still more defective in that respect.

31. Any improvements in dyeing, which have been made in Britain, must be ascribed entirely to the exertions of private individuals, unaided by the patronage of government. In France the case was different; the legislature of that country, as we have already stated, not only appointed proper persons to superintend officially the practice of dyeing in all its departments, but held out suitable rewards for the encouragement of such individuals as should contribute by their discoveries to the progress of the art. The beneficial effects of this liberal and enlightened policy were quickly felt in the numerous improvements in dyeing, which were suggested from time to time by the eminent men who filled these official situations; and it is certainly matter of regret, that no appointment of the same kind has ever been proposed in our own country, where so much importance is attached to arts and manufactures. We are supported by the authority of Mr Anderson* and Mr Home,† in maintaining that the superior brilliancy of colour, which distinguishes several articles of French manufacture above those of other nations, is greatly owing to this fostering care of government.

32. But though the British government has hitherto neglected to encourage an art, upon the proper cultivation of which so much of the success of our commercial competition with other nations must depend, a few of our countrymen have devoted their attention to dyeing, and furnished, at their own expense, the most valuable information to the public. Mr Henry of Manchester directed his attention to the subject at a very early period, and published an interesting paper, (which is inserted in the 8th volume of the *Memoirs of the Manchester Society,* "on the nature of wool, silk, and cotton, as objects of the art of dyeing; on the various preparations and mordants requisite for these different substances; and on the nature and properties of colouring matter," &c. This paper is drawn up with the author's usual philosophical precision, and contains many ingenious views, and much useful information. His observations respecting the cause of the durability of Adrianople red, display an intimate acquaintance with the subject, and do great credit to his talents and information. We are indebted to Mr Henry for the first account of the nature of the aluminous mordant. He shewed, that when the acetate of lead was presented to the sulphate of alumine, a double decomposition took place: that the acetic acid quitted the lead, and combined with the alumine, while the sulphuric acid united with the lead, thus forming two new salts, the acetate of alumine, and the sulphate of lead.

33. No original treatise on dyeing, however, appeared in our language, till Dr Bancroft published his excellent work, entitled, "Experimental Researches concerning the Philosophy of Permanent Colours." The first volume of this work appeared in 1794; and the second, which had been long expected with much anxiety, so lately as 1813. The author has furnished the world with the results of an immense number of experiments, prosecuted with unremitting care during a long course of years, and at a great expense. Though he has been preceded by authors of such distinguished ability, as Mr Henry and Mr Berthollet, the new facts and observations which he offers to his readers shew, to use his own words, that he did not find the subject exhausted. His views are often entirely original; and he has detected a considerable number of mistakes into which Berthollet and others had fallen. He has investigated with much ability the action of tartar in the dyeing of scarlet, and proved by the most decisive experiments, that, with cochineal, the salts of tin produced only a crimson, contrary to the statements of that able chemist, who had entirely misrepresented the operation of these substances in the production of the former of these colours. He has ascertained, that scarlet is a compound colour, formed by the superinduction of a crimson upon yellow; and, in consequence of this discovery, he has proposed a method of dyeing this colour more cheaply, more expeditiously, and more durably than by the ordinary process. But the most important service which Dr Bancroft has rendered to the art of dyeing was, the introduction of quercitron as a yellow colouring matter, the use and application of which for dyeing, calico-printing, &c., were exclusively vested in him for a term of years, by an act of parliament passed in the 25th year of his present Majesty's reign. After the term of the act expired, an unsuccessful attempt was made to obtain a renewal of it, on the grounds that the Doctor had exercised his right more beneficially and liberally for the public, than providently towards himself and family; and that
he had also been deprived of a great part of his just profits by various infringements of the act. A bill for that purpose was accordingly passed in the House of Commons, in the 59th of his present Majesty; but it was lost in the House of Lords, in consequence of the strong opposition which it encountered from a great number of persons in the northern part of the kingdom, some of whom had grown rich by the discovery. It does not appear that the public derived much advantage from this alienation of the Doctor’s right, as the bar of question soon rose to three times the price at which he had invariably supplied it, and would have been bound to supply it, for another term of seven years, if the bill had passed in his favour. The policy of sanctioning a monopoly expressly by law may be justly questioned; but every candid and liberal mind will readily admit, that, considering the very important improvements in dyeing which Dr Bancroft has introduced, the long and severe labour to which he has submitted, and the great expense which he has incurred in the prosecution of his inquiries, he is entitled to some higher remuneration for his services, than the country has yet thought proper to bestow.

34. "Of all the arts," says Berthollet, "that of dyeing, perhaps, with respect to its theory, requires the most extensive knowledge of natural philosophy; because it is that which presents the greatest number of phenomena to analyze, of uncertain changes to ascertain, and of relations to establish with air, light, heat, and many other agents, of which our knowledge hitherto has been very imperfect." But these remarks, though certainly well-founded, ought not to discourage. If many facts remain still to be explained, science has already done much in determining the essential circumstances of particular processes, and excluding such as are either absurd or superfluous; in analyzing the substances employed by the dyer, and discovering the causes to which their action is to be ascribed; and lastly, in suggesting the means most likely to improve the art.

35. In the following account which we propose to give of the operations of dyeing, our object is not so much to bring forward a new treatise, as to collect and condense every thing useful that has already been written on the subject; and to present a view of the art, which shall include the most recent improvements, without neglecting the description of those processes which have long received the sanction of experience. In the execution of this plan, we shall freely avail ourselves of the labours of the most approved writers on dyeing, particularly of Berthollet and Bancroft, as well as of the different individuals who may have suggested improvements in particular processes. In short, we shall aim at usefulness rather than novelty, and never introduce theoretical views, unless they have an obvious tendency to simplify or improve practical operations. When facts occur which we cannot explain, we must be satisfied with detailing the process of the art, and wait for further light from experience, before we attempt to reduce them to theory.

SECTION II.

OF COLOURING MATTERS.

CHAP. I.

OF COLOURING MATTERS IN GENERAL.

36 The knowledge of the laws according to which bodies appear of various colours, by absorbing some of the rays of light, and reflecting others, is of very little use to the practical dyer. His object is merely to extract the colouring principle from the substances which form its original basis; to transfer it to the stuff; to modify it by those agents which have been found by previous experiment to affect its nature; and to give it permanency in its new state of combination. Still, however, it may not be altogether foreign to our purpose to take a slight view of the theoretical opinions which are entertained on this subject.

37. The property which bodies possess of uniformly reflecting certain rays of light, constitutes their colour; for all the rays are absorbed, a body appears totally destitute of colour, or black; and when particular rays are absorbed, and others reflected, it seems to be of the colour which the reflected ray is capable of exciting in our organs of vision. When the substances which thus appear coloured are transferred to colourless bodies, they generally communicate to these bodies their particular colour; and when they are transferred to bodies already coloured, they blend or mingle their colour with that of the substance by which they are applied, and give rise to mixed colours.

38. The aptitude of reflecting particular rays of light, seems to depend not so much upon the chemical composition of a body, as upon a certain arrangement, or disposition of the particles of the surface. Many bodies display different colours, according to the particular angle under which they are viewed; while others assume a change of colour, simply by the change of their mechanical condition.

39. Hence it appears that colour ought not to be regarded as a distinct principle, existing separately from the coloured body; but merely as a faculty which the constituent elements of bodies possess of reflecting particular rays of light decomposed at their surface, and which is capable of being modified by changes in the mechanical structure, or in the proportion of the elementary parts. It is therefore impossible to predict, a priori, the colour of a compound body, from a knowledge of the principles of which it is composed. Frequently two colourless bodies form a coloured compound by mixture; and it often happens that two substances, each of which has a very deep colour, are rendered entirely colourless when they are united together. In short, we can only determine by observation and experiment, the colours which shall result from particular combinations of bodies.

40. These views, however, do not altogether accord with the opinions of several eminent chemists, particularly with respect to colours of vegetable origin. Many seem to think that a peculiar proximate principle exists in vegetables, in which their colour generally resides, and to which they owe the name of colouring matter. "In this opinion," as Mr Murray justly observes, "there is a degree of obscurity and vagueness." Colour being, as we have already stated, a secondary quality, which may reside in any principle, and being often exhibited by principles of the most opposite kind, there is no good reason for supposing that there is any distinct principle to which it exclusively belongs. At the same time, it must be admitted that there is apparently a similarity in chemical constitution between certain vegetable products, in which colouring matters reside in the deepest intensity; and that these colouring matters may be detached from their state of combination by the agency of various solvents, and transferred to other substances with which
they appear to have a more powerful affinity, and this
too without our being able to refer the appearances
which take place to any known proximate princi-
ple.

41. These facts, however, by no means authorise
us to conclude that the colouring matter is a separate
and independent principle; all that can be inferred
from them is, that the colouring matter does not uni-
formly exist in combination with any particular proxi-
mate principle, but probably with different proximate
principles, or various combinations of them; though
the present state of chemical analysis does not enable
us to ascertain the composition of the colouring par-
ticles with a degree of precision sufficient to detect the
principles to which they owe their properties. Without
taking any notice, therefore, of the theories which have
been advanced to explain the cause of colour, we shall
be satisfied with presenting a general view of the dif-
ferent colouring matters, and leave to future investiga-
tion the task of discovering whether these colouring
matters form separate substances, or exist uniformly in
combination with some particular proximate principle
as a basis.

42. It has been proposed to divide the colouring
particles of vegetables into extractive and resinous;
but this division is attended with no advantage, and
indeed only serves to convey very imperfect and erro-
neous ideas of their properties, as some of the most im-
portant dyes are not at all affected by the usual solvents
which act upon these two classes of substances. The
truth is, that the colouring particles possess chemical
properties which are peculiar to themselves, and dis-
tinguish them from all other substances; though these
properties are different in different colouring matters.
They unite with acids, alkalies, metallic oxides, and some
of the earthy bodies, particularly alumine. They are
said to precipitate oxides and alumine from the acids
which hold them in combination; but this is doubtful,
or at least the decomposition is very partial. They
more frequently form triple compounds with the salts,
and in this state of combination unite with the stuffs
to which they are presented, in a more intimate man-
ner than they would do without the intervention of
these bodies.

43. The colouring particles do not, however, unite
indiscriminately with these chemical agents, and there-
fore require different solvents suited to their respective
qualities. The most common solvents are water, acids,
and alkalies; alcohol is seldom used, unless when we
wish to act on the colouring matter of very small bod-
ies. Of these substances, water is most extensively
employed, both on account of its abundance, and the
great solving power which it exerts over almost all
colouring matters; alkalies are employed to promote
the solution of the colouring principle contained in indi-
igo, the flowers of bastard saffron, &c.; and the acids
are used in some cases to dissolve colours, and in others
to precipitate the colouring principles from their solu-
tions in alkalies.

44. Before colouring principles are exposed to the
action of a solvent, they ought to be divided as minute-
ly as possible, by mechanical means. This is obtained
by triturating them in a mortar, or by means of a
muller, and afterwards passing them, in a reduced
state, through a fine sieve, that no gross particles may
escape notice. The methods by which the division
of colouring substances is produced, vary according to
the consistence, structure, and volatility of the mat-
ters upon which the operation is performed. In some
cases, the substance containing the colouring principle
is reduced to chips or scales, by means of a sharp in-
strument; in others, it is perfectly sufficient to bruise
it under mullers, in the same manner as tar is ground.
In whatever way pulverization is performed, the op-
eration is attended with the diffusion of a subtle pow-
der through the workshop, which is both injurious to
respiration, and the cause of a considerable loss to the
manufacturer, particularly if the article be expensive.
These disadvantages may be guarded against, by per-
forming the process of trituration in covered places, or
moistening the matters acted upon with water. After
the colouring principle is sufficiently comminuted, it
may be dissolved, without difficulty, in some of the sol-
vents formerly mentioned.

45. With the exception of some colouring matters of
Water, a resinosor or starchy nature, water may be regarded
as a universal solvent of that class of bodies; while it
possesses the important property of forming a very
imperfect union with them, and readily parts with
them again to the stuff. Warm water extracts the col-
ouring principle more copiously than cold water; but
different substances require different degrees of tempe-
rature for that purpose. Some colouring principles
may be dissolved by long protracted maceration;
others require a very gentle heat, and suffer in their
brilliancy by being exposed to too elevated a tempera-
ture; and others still yield but little of their colour,
unless they be raised to a considerable degree of heat.
A knowledge of these circumstances is absolutely ne-
necessary to the dyer, in order that he may conduct his
operations with certainty and success.

46. A great deal has been ascribed to the qualities of
waters used in dyeing, nothing being more common
than to refer the brilliancy of some colours, and the po-
verty of others, entirely to this cause. Without adopt-
ing implicitly all that has been published on this sub-
ject, it must be allowed that waters contribute essen-
tially to the qualities of dyes; and it may be added, that
different colours, and even the same colour in different
states, require that waters of very different natures
should be employed. Rapid and running waters are
generally the purest, and standing waters most impreg-
nated with earthy and saline matters. In some cases,
however, the latter may be used with great advantage
in dyeing; because the putrid animal and vegetable
matters suspended in them, contribute to form ammonia
and sulphureted hydrogen, which precipitate the earthy
and metallic principles.

47. Waters holding calcareous salts in solution, are
particularly prejudicial to the dyeing cotton of a red col-
our. The lime which is precipitated during the pro-
cess attaches itself to the stuff, and obscures the colour
to such a degree that it is almost impossible to revive it.
But if the object be to obtain a dark colour, these salts
are rather beneficial than hurtful, as they tend to in-
crease the body of the red colour and its modifications,
hence they may be used with advantage when it is in-
tended to convert scarlet into crimson.

48. Calcareous salts dissolved in water, not only af-
fact the brilliancy of some colours, but possess the in-
convenience of weakening the solvent which holds them
in solution, and thus extract imperfectly the colouring
principle. It is of consequence, therefore, to be able
to detect the presence of these salts, that we may either
avoid the water which contains them, or correct its pre-
judicial qualities. Chemistry furnishes us with the
means not only of discovering the different ingredients
which exist in water, but of ascertaining with precision
the quantity of each. The salts of lime, the most common earth which is to be found in water, are easily detected by the copious white precipitate which they afford with the oxalate of ammonia, and those of iron by a solution of galls. In general, water which contains earthy or metallic salts, in such quantity as to be injurious, readily decomposes soap by a double affinity: the acid combines with the alkali of the soap, while the earthy basis unites with the oil, and forming an earthy soap which is insoluble, produces the curdling appearance observable on such occasions. If then a water be clear, destitute of taste and smell, and capable of dissolving soap readily, it may be regarded proper for the objects of dyeing; and all waters which possess these properties are equally fit for the purpose. But it may be remarked, that waters which hold the earths mechanically suspended, that is, such as are muddy, are less prejudicial than those which hold them in solution: In the first case, they attach themselves but loosely to the stuff; in the second, they are precipitated in a state of minute division, and combining with the mordant, become intimately united with the cloth.

49. But as it is not always in our power to choose water of the best quality, means have been devised for correcting the injurious properties of this fluid, when it happens to be bad. The most common corrective for this purpose is bran, which is allowed to remain in the water until it acquires a sour taste. Twenty-four bushels of bran are put into a tub or vat that will contain about 10 hogsheads; a large boiler is filled with water, which, when just ready to boil, is poured into the vat: the acid fermentation soon commences, and in 24 hours the liquor is ready for use. Berthollet conceives that the sour water acts by decomposing the carbonate of lime and magnesia, from which its acid, being more powerful, disengages the carbonic acid; and that in this way the earthy sediment, which is occasioned by boiling, is prevented from taking place.

Alkalis.

50. Alkali, the next solvent in order which we mentioned, is employed to dissolve several colours. In general, as Captain remarks, the colours which are produced by fermentation are less soluble in water than alkali. This is the case with indigo, wood, &c. Thus, boiling water dissolves only a ninth-part of its weight of indigo; wood communicates very little colour to this fluid; and annotta can scarcely be dissolved in it at all without the aid of alkali. After the colouring matter has been extracted by an alkali, it is precipitated by the addition of some weak acid.

Acids.

51. Acids are sometimes employed as solvents of colouring principles. The chemical blue of Pernier, or the Saxon blue of dyers, is a solution of indigo in concentrated sulphuric acid. Guhllic has proposed to extract the colour of yellow wood, broom, turmeric, &c. by means of the aceto-citric, and simple acetic acid, or nitric ether and vegetable acids. The nitric and oxy-muriatic acids impart a yellow tinge to all animal substances; and the former of these acids is even successfully employed to communicate to silk and wool a very beautiful yellow colour. The nitric acid produces a similar effect on madder; but the yellow thus developed disappears when the acid is neutralized.

Primary colours.

52. The simple colours, or at least those obtained from the decomposition of light by means of the prism, are seven in number, viz. red, orange, yellow, green, blue, indigo, and violet. These colours are supposed to be homogeneous or simple, because when they are transmitted a second time through the prism, they are refracted without undergoing any further change. This argument, however, is by no means conclusive; for if any coloured ray be composed of two others, each of these must have the same refrangibility, as it is in consequence of this circumstance alone that they could occupy the same place in the prismatic spectrum; and, in that case, a second refraction could not separate them. The truth is, that the prism furnishes only one means of the analysis of light, and merely shows that certain rays differ from others in refrangibility.

53. Before the discoveries of Newton, the red, yellow, and blue, were generally supposed to be primary rays, and the rest to be compound colours arising from their intermixture. Thus, red with yellow, produced orange; yellow with blue, green; and blue with red, indigo. Another hypothesis has been lately advanced by Prieur; and supported by very ingenious reasoning. According to him, the red, green, and violet, are the primary rays; the red and green giving rise, by their intermixture, to orange or yellow, according as the former or the latter predominates; the green and violet forming blue; and the violet and red purple; and thus, by various modifications of the three original colours, all the others are obtained. We shall give an example of the kind of proof which has been adduced in support of this hypothesis. Let one of the rays, as orange, be selected—a colour which is supposed to be a compound of red and green, the former being in excess. If this colour be really a compound of red and green, and if the arrival of the rays to the part of the spectrum which the orange usually occupies be prevented, by the interposition of a substance that allows only the red or the green rays to pass, we ought to find beyond this substance only red or green; on the other hand, if the orange be simple, these rays will pass through neither of the interposed substances, and beyond this we should have only black. The results corresponded with the hypothesis in a great variety of trials. An additional argument was also derived for its support, by combining the red, green, and blue rays, and thus obtaining white light.

54. In a practical point of view, such opinions are of very little moment; and perhaps it may be more useful to attend to those distinctive characters of the colouring principles, which are founded on their chemical relations with the stuffs. Accordingly, Dr Bancroft has suggested the division of colouring matters into substantive and adjutive colouring matters; "the first including those matters which, when put into a state of solution, may be fixed with all the permanency of which they are susceptible, and made fully to exhibit their colours in or upon the dyed substance, without the interposition of any earthly or metallic basis; and the second comprehending all those matters which are incapable of being so fixed, and made to display their proper colours without the mediation of some such basis." (Philosophy of Permanent Colours, vol. i. p. 118.) These terms, though perhaps not altogether unexcepcionable, must at least be admitted to have a reference to real differences between the substances which they are intended to distinguish; and though the advantages which are derived from this arrangement are small but slight, since very few colouring matters are contained under the first head, but most of them under the second, there can be no impropriety in adopting them, particularly as they are intended to express a fact, and not a theoretical opinion. In treating of colouring matters, we shall therefore observe Dr Bancroft's distribution of them; but in describing the processes by
which these are applied to the stuffs, we conceive it will be more convenient, and not less systematic, to follow same arrangement which has a reference to the colours themselves, rather than to the colouring matters from which they are procured. We shall accordingly divide the colours, without any regard to the decompositions obtained by the prism, into simple and compound; meaning by the latter, such as can, and by the former, such as cannot, be produced by the intermixture of other colours. Under simple colours, we shall include red, yellow, and blue; and under compound colours, the various modifications of these which are obtained by mixture or superinduction.

CHAP. II.

Of Substantive Colouring Matters.

I. Of Animal Substantive Colouring Matters.

55. Dr Bancroft has subdivided this class of colouring matters into animal, vegetable, and mineral. The principal dye belonging to the first kind of arrangement, is the celebrated Tyrian purple. The substance which yielded that beautiful colour, was a whitish half-fluid matter, secreted by particular organs in certain univalvular shellfish, and retained by the animal in an appropriate receptacle. The accounts which have been transmitted to us by the ancients respecting the shell-fish in question, are obscure and contradictory. Those of Pliny are the most explicit and intelligible, though they are sometimes inconsistent with each other. He mentions the shell-fish which afforded this dye, under the several names of conchylia, murex, purpura, and buccinum; all of which are also used by other Roman writers. This curious subject has been so ably investigated by Dr Bancroft, that very little further elucidation can be thrown upon it; we shall therefore avail ourselves of his researches, and communicate the substance of them as fully as is consistent with the nature of our work.

56. It appears that Fabius Columna, a Neapolitan nobleman, was the earliest modern writer who wrote a dissertation on the Purpura, which he published in 1616. After being at much pains to elucidate and reconcile the different passages of ancient writers on this subject, he came to the conclusion that there were two kinds or genera of shell-fish used for procuring the purple dye, viz. the purpura and buccinum; that the term conchylia signified generally all the species of purpura, and sometimes the purple colour itself; and that the term murex was also used in the same generic sense. Pliny, indeed, expressly mentions, that all the shell-fish yielding the purple and other lighter colours of the conchylia, are in matter the same, and differ only in temperament; that they are of two kinds, one being called buccinum, from its resemblance to the instrument called the horn, and the other purpura. The former he describes as being round at the aperture, and having a serrated margin; the latter as having a projecting pipeshaped beak, with a lateral winding cavity, through which it puts forth its tongue. He mentions also that the body of the shell of the purpura is muricated or armed with seven rows of spires, which are wanting in the buccinum. He adds, that the buccinum adheres to rocks and large stones, whence alone it can be collected.

57. The best purpura found on the coasts of Asia were caught in the sea adjoining to Tyre; on the African coast, the best were those of Meninx and the Ge-tulian shores; and the best on the coasts of Europe were found at Laconica. Pliny informs us, that the Tyrians took the finest out of the larger shells, in order to extract the purple more effectually, but obtained the colour from the smaller by grinding them in mills. He adds, that when the purpura were caught, the receptacle which contained the dyeing liquor was taken out and laid in salt for three days; and that after a sufficiency of the matter had been collected, it was boiled slowly in leaden vessels over a gentle fire, the workmen skimming off from time to time the fleshy impurities. This process lasted ten days, after which the liquor was tried by dipping wool into it, and if the colour produced by it was defective, the boiling was renewed. Pliny afterwards erroneously represents the liquor of the buccinum as only yielding a fugitive colour, and says that it was usually mixed with more than half as much of the liquor of the purpura, which of itself gave a very dark purple; and that the mixture produced a beautiful amethyst colour, the latter giving permanency to the former, and being in return brightened and enlivened by it. We rely on the same authority, that the Tyrians produced their purple by first dyeing the wool with the unprepared or greenish liquor of the purpura, (another name which he applies to the purpura,) and afterwards in the liquor of the buccinum, and that the resulting colour was deemed most perfect when it resembled that of coagulated blood.

58. It is farther stated by Pliny, that it not being thought sufficient to communicate the colour of the amethyst to wool, it became customary to dye it again with the Tyrian purple; and that in reference to this circumstance, the compound colour produced by this refinement in luxury, was called Tyrriamethystus. He adds, that, not content with thus combining colours obtained from the ocean, recourse was also had to those produced on the land; and that wool or cloth dyed crimson from the coccus (kermes) was afterwards made to imitate the Tyrian purple, in order that it might assume the colour which was named hysginus, after a flower so called. Other colouring matters were employed, sometimes to economize, and at other times vary the effects of the colours of the purpura and buccinum. Among these, Pliny enumerates fucus mari- nus or anchil, and the anchusa tinctoria or alkanet, both of which are still used as dyes. By these and other means, the purple colour was made to assume a variety of shades, some inclining more to the blue, and others more to the crimson.

59. Under the history of dyeing, we took notice of the restrictions which had been imposed upon the use of the Tyrian purple, and mentioned other circumstances which gradually led to the total neglect of that celebrated dye; we shall now describe a little more minutely the methods of communicating that colour, by means of shell-fish, which have been employed in modern times. In the year 1683, Mr William Cole of Bristol being at Minehead, he was there told of a person living at a sea port in Ireland, who had made considerable gain by marking with a delicate durable crimson colour, the fine linens of ladies and gentlemen sent to him for that purpose, and that this colour was made by some liquid substance taken out of shell fish. Mr Cole, being a lover of natural history, and having his curiosity thus excited, went in quest of these shell fish; and after trying various kinds without success, he at length found considerable quantities of a species of buccinum on the sea coasts of Somersetshire, and the opposite coasts of South Wales. After many ineffectual endeavours, he...
discovered the colouring matter placed in a "white
vein lying transversely in a little furrow or cleft next
to the head of the fish, which," says he, "must be dig-
ged out with the stiff point of a horse hair pencil, made
short and tapering, by reason of the viscous clamminess
of the white liquor in the vein, that by its stiffness
it may drive in the matter into the fine linen or white
silk" intended to be marked. Letters or marks made
in this way, with the white liquor in question, "will
presently," adds he, "appear of a pleasant green colour,
and if placed in the sun, will change into the following
colours, i.e. if in the winter, about noon, if in the sum-
mer, an hour or two after sunrise, and so much before
setting, (for in the heat of the day in summer, the col-
ours will come on so fast that the succession of each
colour will scarce be distinguishable;) next to the first
light green will appear a deep green, and in a few
minutes this will change into a full sea-green, after which
in a few minutes more, it will alter into a watery blue.
and from that, in a little time more, it will be of a par-
nish red, after which, lying an hour or two, (supposing
through this sun's shining,) it will be of a very deep
purple red, beyond which the sun can do no more." He re-
marks, however, that "these changes are made faster or
slower, according to the degree of the sun's heat;" "but
then," adds he, "the last and most beautiful colour, af-
fter washing in scalding water and soap, will (the mat-
ter being again exposed to the sun or wind to dry) be
much a differing colour from all those mentioned, i.e.
a fair bright crimson, or near to the Prince's colour,
which, afterwards, notwithstanding there is no styptic
to bind the colour, will continue the same, if well or-
dered, as I have found in handkerchiefs that have been
washed more than forty times, only it will be some-
what alloyed from what it was after the first washing."

60. M. Cole sent some of the linen marked in this
way to Dr Plot, then one of the secretaries of the
Royal Society, in November 1684; which was soon af-
ter shewn to Charles the Second, who admired it great-
ly, and desired that some of the liquor might be sent
to town, in order that he might witness its effects. But
before this could be done, the king died, and it ap-
tains that little further interest was at that time excited
about the matter. After an interval of twenty-four
years, M. Jussieu found a small species of buccinum
on the western shores of France, and presented some
of them to him in 1789 to the Royal Academy of Sciences at
Paris; and in the following year, Reaumur discovered
great numbers of the same shell-fish on the coast of
Poitou. Reaumur observed, that the stones and little
sandy ridges round which they had collected, were
covered with a kind of oval "graines," some of which
were white, and others of a yellowish colour; and hav-
ing squeezed some of them upon the sleeve of his shir-
t, he was agreeably surprised, in about half an hour,
to find it stained of a fine purple colour, which he
was unable to discharge by washing. He next collect-
ed a quantity of these grains, and carrying them to
his apartment, bruised and squeezed different parcels
of them upon bits of linen; but, to his great surprise,
after waiting two or three hours, no colour appeared
upon the spots wetted with the liquor. Unable to con-
template the reason of this disappointment, and having
almost determined to return again to the sea-shore, and
repeat the experiment on the same plan as before, he
chanced to perceive some purple spots, occasioned by
drops of the liquor which had accidentally fallen upon
a part of the plaster of Paris with which the sides of
the window were covered, and which having been more
strongly acted upon by the light than the bits of linen
wetted with the same liquor in the interior part of the
room, had become purple, though the day was then
cloudy. He afterwards made a variety of experiments
with the liquor of the buccinum; but as he was, from
the outset, impressed with the notion that the conver-
sion of it to purple was occasioned by some mechanical
action of the air, he never discovered the true cause
of the production of that colour.

61. Reaumur conceived the grains in question to be
the eggs or spawn of some fish, but whether of the bucci-
um or any other species, he was uncertain, and under
this uncertainty he proposed calling them œufs de pour-
pre, eggs of purple. The colour which they produced
was at least equal, if not superior, in beauty, as well as
durability, to that of the buccinum; though the colour-
ing matter of the latter was much thicker, and passed
less quickly through the different shades of colour, on
exposure to the light of the sun. He also found that
the liquor of the buccinum tasted as hot as the hottest
pepper, whilst that of the purple eggs was pleasant. But
when the latter was so viscous, that, when topically ap-
plied to linen, it did not run; and as the grains were,
according to his accounts, so plentiful, that one man
might collect half a bushel of them in a few hours,
there is certainly reason to conclude, says Dr Bancroft,
that they would be highly useful, at least in calico-
printing, where their liquor might be applied with the
greatest facility, both for pencilling and printing, as a
substantive topical colour, and where a small quantity
would go far, especially upon fine muslins.

62. About the beginning of the year 1736, Duhamel
discovered the purpura in great abundance upon the
cost of Provence. He found the viscid colouring mat-
ter of the fish to be white, except in a few instances in
which it was green, an appearance which he ascribed
to disease. The white liquor being exposed to the sun's
rays, assumed the following colours: 1. A pale yellowish
green; 2. An emerald green; 3. A dark blueish green;
4. A blue with a tinge of red; 5. A purple; and these
changes all happened in less than five minutes. In all
the experiments which were made with the purpura,
the presence of light was found essential to the for-
mation of the purple colour; and the effect was produced
most expeditiously when the influence of the sun's rays
was most powerful.

63. Little doubt can now be entertained of the identity
of the shell fish employed by the ancients, and those
discovered by Cole, Reaumur, and Duhamel. Both Ari-
stotle and Pliny have informed us, that the liquor of
the purpura was white; and the latter also remarks, that
the purple colour which it afforded was not instantane-
ously produced, but after a succession of several col-
ours, of which green was one. We have also a de-
scription of the manner of catching the shell fish, em-
ployed for the purple dye, written by an eye witness,
Eudocia Macrembolitissa, daughter of the emperor
Constantine the Eighth, who lived in the eleventh
century, while the knowledge of dyeing the Tyrian purple
still remained; and from which it appears, that the
ancient purple did not acquire its due lustre and per-
fecion until it had been exposed to the sun's rays.

64. Berthollet is inclined to believe, that the changes,
cause of the change of colour of the purpura and buccinum
under the sun, go by exposure to the sun's rays, are owing to
the

* Color austerus in Glauco, et irascensce similis mari. Lib. ix. cap. 36.
Dyeing.

II. Of Vegetable Substantive Colours.

60. The substantive colours obtained from vegetables are more numerous than those which are of animal origin, and far more interesting to the dyer. Of these, the most singular, as well as the most important, is indigo, a blue colouring substance extracted from a genius of plants known by the name of indigofera and indigo, which are cultivated for its production in America and the West Indies. Indigo consists of a peculiar colouring matter, which may be denominated its basis, and which being combined with a certain portion of oxygen, is, during its union, insoluble by any means unless such as exert an agency more or less destructive on the basis itself. This basis is, in its uncombined state, entirely destitute of colour; and seems to be formed by certain peculiar secretory organs, possessed by a few particular plants. Dr Bancroft states, that the expressed juice of the leaves of the indigo plant communicates to calico a greenish tinge, which in dyeing approaches to blue, and ultimately assumes that colour; and that repeated applications of it to the same spot, increase the deepness of the shade, and at last produce a full blue. He suspects, however, that the colouring matter of the indigo, when thus applied in its native state, does not absorb so much oxygen, as when it undergoes the fermentive process by which it is usually prepared for the purposes of dyeing.

61. In another part of this work, (see Indigo,) General Bancroft shall describe the various processes which are properties employed for preparing indigo, and confine ourselves at present to a description of its nature and properties as a dye. In its prepared state, indigo is of a very rich blue colour, which varies, however, in its shade, in different specimens. This difference seems to be owing not so much to any real difference of quality in the colouring matter, as to the foreign substances with which it is occasionally united. When indigo is pure, it is light and friable; tasteless, and almost destitute of smell; and having a smooth fracture. Some varieties are lighter than water; and the lightest is generally, the purest. Indigo is frequently adulterated by adding to it gummy, resinous, and earthy substances, particularly an extract from the fruit of the embryop- teris glutinifera, denominated gaub in the East Indies. Both its weight and its purity are affected by the presence of lime, which having been used in excess, as a precipitate, had subsided with the colouring matter, and carried down other impurities along with it.

62. The finest and most valuable indigo was formerly brought from Guatimala; but since the manufacture of this commodity engaged the attention of the British inhabitants in the East Indies, indigo superior even to that of Guatimala has been imported, in considerable quantity, from that quarter. Dr Bancroft enumerates three varieties of American indigo: of which the first, called by the Spaniards flora, has a very fine blue colour; the second, which bears the name of color satiente, is violet; and the third, named corti-color, is copper-colour-
ed. When the first of these, he adds, sells at 9s. a pound, the second is commonly thought to be worth 7s. and the third 5s. 6d. The finest blue indigo from the East Indies commonly sells 20 per cent. higher even than the finest glowing, (though the last probably contains nearly as much colouring matter as the first); and 70 or 80 per cent. higher than the best copper-coloured.

72. Berthollet has proposed a method of determining the relative values of different specimens of indigo, by dissolving equal portions of each in sulphuric acid, and afterwards destroying their colour by means of oxymuriatic acid; that specimen being considered as the most valuable which required the greatest quantity of oxymuriatic acid to destroy its colour. Dr Bancroft has suggested another method of ascertaining the same thing, which is more simple, and perhaps not less accurate. He proposes to mix equal portions of different solutions in sulphuric acid, and, after diluting these with a certain quantity of water, to compare the shades of colour possessed by the several mixtures.

73. According to the experiments of Bergman, one part in nine of indigo is soluble in water by boiling; and this part appeared to consist of mucilaginous, astringent, and saponaceous particles. The astringent particles are precipitated by solutions of alum, sulphate of iron, and sulphate of copper. M. Quatramore also has separated the soluble parts by means of water. He mentions, that their quantity is greater in proportion as the indigo is inferior in quality, and that the residue, after this operation, is equal to the finest indigo. He accordingly proposes to purify indigo of inferior quality by boiling it in a bag, renewing the water till it acquires no more colour. For the chemical properties and composition of indigo, see CHEMISTRY, vol. vi. p. 112.

Green indigo. 20.

74. About the year 1790, Mr Alderman Princep, who had then lately returned from India, presented Dr Bancroft with a specimen of indigo which he had procured in that country, and to which he gave the name of green indigo. Dr Bancroft at first entertained the hope of its proving the same kind of colouring matter, as that obtained by the inhabitants of Cochin-China from a plant called tan, which, when macerated and fermented like indigo, yields a green fecla capable of dyeing a beautiful and lasting emerald green. The specimen was too small, however, to enable Dr Bancroft to examine its properties with sufficient precision; but he ascertained, that it differed in several respects from common indigo, and particularly that it did not produce, like that substance, a fixed colour on linen or cotton by topical application. See Bancroft, i. 264.

Baraant verte. 20.

75. About three years afterwards, considerable attention was excited, among those who took an interest in the improvements of dyeing, to another species of indigo which had been sent from Calcutta, under the name of baraut verte. It was described to be a simple substance, and to have been prepared with water and fire only, "from an indigofeorous plant, an ever green, with leaves somewhat resembling those of the laurel, bearing large clusters of small yellow flowers, and producing seeds in large pods pointed at the end." and it was added, "that the seed did not vegetate in Bengal." It was also represented as giving a durable light green colour, without any mordant or basis, to silk and wool. Dr Bancroft soon procured a specimen of this colouring matter, and, with his usual zeal, set about an examination of its properties. After making a few experiments upon it, he discovered that it was a species of impure indigo, and that it owed its green colour to the presence of an olive-coloured matter, which, on being burnt, appeared to consist chiefly of carbon. The manufacture of this dye was therefore abandoned.

76. Pastel, or woad, also affords a blue colouring matter, which possesses properties somewhat analogous to those of indigo. Two species of plants are distinguished under this name, the isatis tinctoria, and the isatis Lusitanica. The former is chiefly cultivated in Languedoc, Provence, and Normandy; and also in some parts of England. The plant, after being cut down, is washed in a running stream, and then dried in the sun, as speedily as possible. When it is dried slowly, it is in danger of being spoiled by the colour becoming black. It is next carried to the mill to be ground, and reduced to a paste. In this state it is formed into heaps, which are covered to secure them from rain. At the end of a fortnight these heaps are opened, and beaten, to produce a thorough intermixture of the crust formed on the surface with the internal part. It is then made into round balls, and placed in a situation where it may be freed from the moisture which still adheres to it. The balls are afterwards heaped above one another, to undergo the process of fermentation, and evolve the blue colour yielded by the plant. As the process advances, the smell of ammonia is exhaled, and the balls are gradually reduced to a coarse powder; the state in which woad occurs in commerce.

77. Pastel affords, without the assistance of indigo, a blue colour of considerable permanency, but little lustre. As it yields a small quantity of colouring matter in comparison of indigo, and of inferior beauty, the use of woad, as a dye, is now almost totally abandoned. Astruc affirms, that pastel treated like indigo yields a colouring matter which greatly resembles indigo; and Chaptal states, that, from experiments which he made in 1795, with the view of adding some vegetables to the list of those which furnish blue colours, he discovered that goats rue, sawn foin, chick peas, and lucern, yielded a blue colour when treated like indigo, which he did not, however, succeed in precipitating. D'Ambourney also attempted to procure indigo from pastel. He succeeded by letting fresh leaves of pastel ferment in a certain quantity of water; taking out the leaves, and pouring solution of caustic alkali into the liquor, and afterwards filtering. The fecla which remained on the filter, he says, resembles Carolina indigo. Thirty-five pounds of fresh ripe pastel leaves yielded eight ounces of fecla.

78. Turmeric is enumerated by Dr Bancroft among the vegetable colouring matters which he calls substantive; though the little durability which it possesses, as a dye, scarcely entitles it to that epithet. Turmeric is the root of the curcuma, of which there are two species, the rotunda and the longa. The former is chiefly cultivated for the use of the dyer. Turmeric is of a very rich colour, and surpasses every other yellow colouring matter in beauty; but it has a very slight attraction either to stuffs, or the mordants which are usually employed to give fixity to colours. The root must be reduced to powder to be fit for use. It is sometimes employed to give the yellows made with weld a golden cast, and to communicate an orange tint to scarlet; but its effects soon disappear.

79. Mr Bayley, who, in 1795, was extensively engaged in dyeing silk handkerchiefs to imitate those of India, informed Dr Bancroft that the yellow spots were produced solely by a tincture of turmeric made by di-
DYEING.

Dyeing six pounds of the powder of turmeric in a gallon of malt spirits, and afterwards by a press separating three quarts of a rich tincture, which cost about four shillings the quart. The tincture was applied topically, and without thickening, to the spots of the silk handkerchiefs, which in the dyeing had been reserved white by the usual means. Dr Baneroff found that a tincture of turmeric so obtained, and gummed, when applied topically to calico, produced a beautiful yellow, which, by washing with soap, became red; but being well rinsed, and exposed to the atmosphere, it recovered its former colour, and retained it after several washings. See Baneroff, vol. i. p. 278.

Annotta.

The seeds of the bixa orellana, which grows spontaneously in different parts of Guiana, are covered with a reddish pulp, which is collected and exported to different parts of Europe under the names of anotta, anotta, and ronce. This substance is sometimes employed for dyeing silk; and occasionally for cotton; but in either case it adheres but slightly to the stuff. It partakes so much of a resinous nature, that it is very imperfectly dissolved in water. It is therefore usual to employ at least its own weight of potash to increase its solubility, and afterwards to immerse, in the solution, the silk or cotton to be dyed, without any mordant. The colour of the anotta thus dissolved may be rendered of various shades of yellow, by destroying, by means of citric acid, the effects of the alkali. In dye-houses, where much anotta is consumed, it is put into a copper cullender, having very small holes, (being previously reduced to a state of minute division,) and the whole immersed in a copper filled with tepid water. The anotta is stirred and diffused by a stick in the form of a pestle, and passes into the bath through the holes of the cullender. The strainer is then filled with ashes from the dregs of wine, which is treated in the same manner; after which the bath is well stirred, and made to boil up, two or three times when the boiling is stopped by throwing in cold water. When the bath is not sufficiently alkalized, it produces a brick or red colour; in which case an additional quantity is applied, it is made to boil up, and the boiling stopped as before with cold water. (Chapital) In Britain, anotta is scarcely employed for any other purpose than in giving yellowish-brown tints to cotton.

Carthamus.

81. Carthamus, or bastard saffron, (carthamus tinctorius,) of which the flower only is useful in dyeing, is an annual plant, cultivated in the southern parts of Europe, Egypt, and the Levant. The flower of carthamus affords two colouring matters, one of which is soluble in water, and yields an inferior yellow; the other is resinous, and obtained by the action of the fixed alcohols. The latter alone is valuable, as it furnishes a red of greater delicacy and beauty than can be procured from any other colouring matter, though of but little durability.

82. The colour is obtained by tying up the flowers in a linen bag, and then subjecting them to maceration and pressure in clear running water, until all the yellow colouring matter which they contain is dissolved, and washed away. After this has been done, the flowers are again macerated in a solution of pure soda, just sufficient to dissolve and extract the resinous colouring matter, which is separated by draining, and the repeated effusion of portions of water, until it is wholly dissolved and carried off. A solution of the colouring matter being thus obtained, the soda is neutralized by an acid; the citric is usually preferred, and it is thought to answer the purpose best, when it is in the state in which it exists in lemons, or limes beginning to spoil. Next to the citric acid, some have recommended that of tamarinds and tartar; though Bergman prefers the sulphuric, if it be not used in excess. Scheffer affirms that the acid juice of the mountain ash produces a better, and more durable colour than even the citric acid. The expressed juice after being allowed to ferment, is bottled up, and becomes fitter for use the longer it is kept.

83. The rose colour of carthamus, extracted by soda, and afterwards detached from the alkali by citric acid, affords the basis of the beautiful paint known by the name of rouge. The colouring matter being slowly dried in the shade, is finely ground with the purest tale, and in this state is applied to give to the cheeks the lue of health and beauty, by those females who are distrustful of their native charms.

84. Archil, or archill, is a colouring matter, obtained from several species of lichens. When it is prepared for the purposes of dyeing, it is in the form of a paste, and of a red violet colour. The most valuable is extracted from the lichen roccella, (Limn,) which grows at Cape Ver, and the Canary Isles, on the rocks near the sea. Dillenius has endeavoured to shew, that this plant is the same that was used by the ancients, and held by them in such estimation, that the colour, which it afforded was reckoned more beautiful, when first dyed, even than the Tyrian purple. It is mentioned by Pliny under the name of fucus marinus, and was used in his time as a ground for that colour.

85. The knowledge of archil as a dye, was lost, however, in Europe, till about the beginning of the 14th century, when it was restored by a native of Florence, who had become acquainted with its properties during his residence in the Levant. He communicated the information he had acquired to his fellow citizens, and for a considerable time the Florentines enjoyed the exclusive use of it as a dye, as they purchased all that could be procured of it, among the islands of the Archipelago, and on the shores of the Mediterranean. After the discovery of the Canary Isles, the lichen, which yielded the archil, was found in great abundance on their coasts, and by this means the other nations of Europe were relieved of their dependence upon Italy to supply the commodity. The plants which yield this colouring matter, have also been discovered in great abundance at the Cape Verde Isles; and as they had been allowed to attain their full maturity, they were found to be richer in colouring matter than any which had been previously known.

86. Micheli has given an account of the method of preparing archill, conformable to the practice of Florence. The plant was first reduced to a fine powder, and after being passed through a sieve, was moistened slightly with stale urine. The mixture was stirred once a day, and a certain portion of soda added each time, till it acquired a dode colour. It was then put into a wooden cask, and covered with a sufficient quantity of urine, lime water, or a solution of gypsum; and in this state it was retained until wanted by the dyer. In the description given in Picotho, (a work which we mentioned under the history of dyeing,) sal ammonic, sal gom, and salt petre, are added in the preparation; but Heltot thinks, from experience, that lime and urine are the only ingredients necessary; and that the mixture ought to be frequently stirred, adding, at the same time, fresh quantities of these. It is proper when the process is completed, says Berthollet, to allow the vo-
DYING.

Substantive Colouring Matters.

Archil is a late alkali which has formed, to evaporate, that the archill may have the violet smell of that which is well prepared. To preserve it any length of time, however, it must be kept moistened with urine.

The best kind of archil is extracted from the roccella, or orchella; but this colouring matter is obtained from several other species of lichen. The French have long employed for this purpose a kind of lichen called perelle, which commonly adheres to volcanic stones or productions. The plant in question has, generally represented to be the lichen parlellus of Linneaus; but this supposition is disproved by a memoir, of M. Coecq lately published in the 81st vol. of the Annales de Chimie. He states, that in Auvergne, where the perelle is principally gathered, the true lichen parellus is called la pommelée, and is always rejected as unfit by the persons employed for this purpose. M. Coecq describes, in the same memoir, the process by which the perelle is prepared at Clermont for the use of the dyer. It appears, that the perelle is macerated and fermented in wooden troughs, which are commonly about six feet in length, two or three in breadth, (contracting towards the bottom,) and about two feet in depth. Each trough is furnished with a cover, which fits it exactly, and retains as much as possible of the volatile alkali of the human urine. About 200 lbs. of perelle and 240 lbs. of urine are mixed together in each trough, and afterwards stirred three hours, during two days and nights, taking off the cover only as often and as long as is necessary for the stirring. On the third day, 10 lbs. of sifted and stacked lime must be added, and well mixed, together with a quarter of a pound of arsenic, and an equal weight of alum. The workmen must avoid the fumes of the arsenic as much as possible, for some hours after its admixture. The stirring is then to be repeated several times, once every quarter of an hour, and afterwards every half hour, till the fermentation is established; when this is the case, the mixture need not be stirred more frequently than is necessary to prevent a crust from forming on the surface, which, by obstructing the fermenting process, would resist the complete evolution of the colour. After the fermentation has continued 48 hours, it commonly begins to diminish, and must be renewed by the addition of two lbs. more of sifted lime, and the stirring continued once every hour until the fifth day, when the frequency of stirring may be gradually diminished. After the eighth day, it is sufficient to stir the mixture every six hours, extending the process a fortnight, and even in some cases three weeks longer. The colouring matter thus prepared, is afterwards to be kept moist in close casks. It improves during the first year; suffers little change during the second; the third, it begins to decline, and becomes inferior in quality afterwards.

89. The colours obtained from cudbear prepared by these processes, possess great beauty and lustre, at first, but they quickly fade, and ought never to be employed unless for the purpose of heightening the brilliancy of some more permanent dye. The colour extracted from the roccella, or orchella, is more beautiful and less fugitive than that yielded by any other species of lichen; but none of these colours are lasting. Cudbear is chiefly employed in this country to give body and lustre to the blues dyed with indigo; it is also sometimes used as a ground for madder reds. It stains marble of a durable violet colour. Dufay says, that he has seen marble stained with this colour unaltered at the end of two years.

90. The infusion of archil is of a crimson, inclining to violet. Acids impart to it a red colour: but as it contains ammonia, by which its natural colour has been already modified, fixed alkalies produce little change on it, only rendering its colour somewhat deeper, and more inclined to violet. Alum forms with it a dark red precipitate, without rendering the colour more permanent. The nitro-muriate of tin makes the colour dyed with it to approach nearer to a crimson, which is less fugitive than when that ingredient is not employed.

91. Besides the lichens, whose colouring matter is prepared with ammonia, some of them afford substantive dyes less beautiful, but more permanent, by mere boiling with water. Of these, the musc pulmonarius of Caspar Bau- line, or the lichenoides pulmonarius reticulatum vulgare marginulus petitieris of Dillenius, known in the northern parts of England by the name of rags, or stone-mg, dyes, without any mordant, a very durable dark-brown colour upon white wool or cloth; and a fine lasting black upon wool or cloth which has previously received a dark blue from indigo. See Bancroft, Perm. Col. i. 305.

* This is contrary to what is recommended by Berthelot.
III. Of Mineral Substantive Colours.

92. The greater number of mineral substances used in dyeing, are employed chiefly with a view of attaching colouring matters to stuffs, or of heightening their lustre after they have been so applied. Some of them, however, particularly iron and copper, are occasionally employed for giving substantive colours.

Iron.

93. Iron, in every form of its solution, has a strong affinity for linen and cotton, and readily combines, in the state of an oxide, with their fibres. The colours which it affords vary with the degree of oxidation; but as the oxide, in all its combinations, is disposed to attract more oxygen from the atmosphere, these colours all terminate in the rusty colour commonly called iron-mould. This absorption of oxygen, being a kind of slow combustion, renders the oxide corrosive, and gradually injures the texture of the cloth. The rigidity which it occasions in the fibres, also renders them more brittle, and less durable. Hence iron-moulds at last produce holes. This injurious property of the oxide of iron, is in some degree counteracted by combining the oxide with other substances; but there is reason to fear, that, in every condition, the oxide of iron is hurtful to stuffs. It is to this property that the rottenness so generally complained of, with respect to the black dye, is to be ascribed.

94. The oxide of iron is usually applied to linen or cotton in combination with some acid. Vinegar was usually employed for this purpose; and the resulting salt, the acetate of iron, has long been known to dyers under the name of iron liquor. Another acid has of late been frequently substituted for the vinegar, called the pyroligneous, which is distilled from wood, and is in reality the acetic acid in combination with a portion of empyreumatic oil. This compound acid dissolves iron better than the acetic, and forms a salt which is more useful in dyeing than the acetate. The oxide combines with the acid at different stages of oxidation; but the resulting solution forms the most intimate and permanent union with the fibres of linen and cotton, when the oxidation is greatest. M. Chaptal has ascertained that the different buff colours, and the imitations of mackeen, may be greatly improved by combining the oxide of iron with alum. He accordingly first impregnates the linen or cotton with a solution of the oxide of iron in the pyroligneous, or some other vegetable acid,marking three degrees on the acometer of Beaume, and, after wringing it properly, plunges it immediately into a solution of potash marking two degrees, with which a saturated solution of alum has been mixed, but so as not to precipitate the alumine. By this mixture, the colour of the oxide is heightened, and the cloth acquires an agreeable, smooth, and soft appearance.—See Ann. de Chim. xxxi. p. 270.

95. The application of potash conjointly with an oxide of iron, is stated by Dr Bancroft to have been practised at Manchester for almost half a century. The iron was usually, but improperly, dissolved in aquafortis, as this acid acts with great energy on the fibres of linen and cotton, and soon destroys their texture.

96. The colours produced by iron, though very durable, are liable to be affected by the infusion of tea, and other substances which contain the gallic acid. The spots occasioned by these may, however, be removed by an oxymurate of potash or lime.

Copper.

97. Dr Bancroft has proposed to employ the oxides of copper as substantive colours, though the advantage to be derived from their use in this respect is extremely doubtful. He mentions that he had produced accidentally, and fixed permanently upon calico, a brownish red oxide of copper, nearly resembling the ruby copper ore in colour, which withstood repeated washing with soaps, and six weeks exposure to the atmosphere, without alteration. He thinks that this colour may prove useful by simple topical application, in calico printing; but he has not examined it sufficiently to give a decided opinion on the subject.

98. The green colour exhibited by most of the preparations of copper arises from the absorption of oxygen, for which the oxides of this metal have a strong affinity. It does not appear that any of the solutions of copper or its oxides, can be applied simply to linen or cotton, so as to resist the action of soap, though they suffer but little change from exposure to the sun and air. If liquid ammonia be saturated with copper, and thickened with gum, it may, by simple topical application, be fixed upon linen or cotton, when, by an evaporation of a part of the volatile alkali, and the absorption probably of both oxygen and carbonic acid, its blue colour will be changed into a green resembling that of verdigrise, or rather that of the malachite, which will sufficiently resist the impression of sun and air, and bear a considerable number of washings with soap, without being affected thereby. It may therefore, says Dr Bancroft, be usefully employed in this way, especially upon fine muslins, by reason of the great delicacy of its colour, and the facility of its application.—Perm. Col. i. p. 320.

99. The oxides of various other metals have been proposed to be used in dyeing; but it does not appear that any of them can be usefully or extensively employed as colouring matters upon cloth.

CHAP. III.

Of Adjective Colouring Matters.

I. Of Animal Adjective Colours.

100. The most important and valuable matter belonging to this class, is the coccus cacti of Linnaeus, or cochineal. We have already described the methods which are employed for rearing this insect, and shall therefore confine ourselves at present to an account of its qualities as a dye. See COCHINEAL.

101. Two kinds of cochineal are employed in dyeing: Cochineal, they are distinguished in Mexico by the Spanish terms grana fina, and grana sylvestra. The first variety, being of a larger size, and yielding a greater quantity of colouring matter, is reckoned the most valuable; the other is smaller, and covered with a downy substance, resembling cotton, which increases its weight, without being of any use in dyeing.

102. Cochineal which has been properly prepared, and externally carefully kept, is of a greyish colour, inclining to purple. The greyish colour is occasioned by a powder, which covers the insect in its natural state, and part of which still adheres to it; the purple shade is owing to the colouring matter extracted by the hot water in which the insect has been killed. Cochineal retains its properties for a very long time if it be properly kept. Hellot says, that he made some experiments with a quantity of it which was 150 years old, and that its properties as a dye were unchanged.

103. The colouring matter of cochineal may be extracted by water. The decoction is of a crimson colour, the solution of which inclines to violet. A little sulphuric acid being added...
to it, causes the liquor to assume a red colour, inclining to yellow, and forms a small quantity of a beautiful red precipitate. Muriatic acid produces nearly the same effect, but no precipitate. A solution of tartar converts the liquor into a yellowish red, and slowly produces a small quantity of a pale red precipitate. The supernatant liquor retains a yellow tinge, which is changed into purple by the addition of an alkali. The precipitate is quickly dissolved by the alkali, and the solution becomes purple. A solution of alum heightens the colour of the infusion, renders it redder, and produces a crimson precipitate. A mixture of alum and tartar produces a bright lively colour, inclining to a yellowish red. A solution of muriate of soda, (common salt), renders the colour somewhat deeper, but does not make the liquor turbid. Muriate of ammonia gives a purple tinge, without any precipitate. Sulphate of soda produces no change. The acetate of lead forms a purple, inclining to violet. Nitrate of lead, a delicate lively colour, between red and cinnamon, but inclining most to the former. The sulphate, nitrate, muriate, and acetate of iron, produce a dark violet, and even a full black colour, when they are used in sufficient quantity. The salts of copper and mercury debase the colouring matter of cochineal. Nitrate of zinc gives a lively bright blue colour, approaching to purple. Muriate of zinc, a colour like the last, but more of a purplish tinge. The salts of bismuth produce indifferently colours; and the same remark may be applied to the salts of cobalt, nickel, tungsten, antimony, and manganese.

104. Of all the metallic salts which affect the colour of cochineal, the most important is the oxide of tin. About the year 1650, it was discovered by the accidental falling of a solution of the nitrate of tin into a decoction of cochineal, that the colour of the latter instantly passed from purple to a vivid scarlet. Different salts of tin produce different effects; but we must reserve the particular consideration of their properties, until we come to examine the nature of mordants.

105. When alum is added to a decoction of cochineal, it combines with its colouring matter, and forms the beautiful lake called cARMINE. A certain proportion of an- taur, a bark brought from the Levant, of a colour paler than cinnamon, and in general, chouan, the seed of a plant likewise brought from the Levant, are added. Berthollet supposes that these two substances furnish, with alum, a yellow precipitate, which serves to brighten the colour of the cochineal lake. Carmine was formerly prepared from kermes, from which it takes its name, and the nature of which we shall now consider.

106. Kermes (coccus ilicis), is an insect found in several parts of Asia, and the south of Europe. It appears to have been employed at a very early period as a dye, and was known to the ancients by the name of coccus baptricus, coccus infectius, granium tinctorium. The term kermes is supposed to be of Arabic origin, and signifies a little worm. The Italians afterwards formed from it the words cernisi, cremesino, and cermesino; and the French those of carmesin, carmine, and cromosi. The English words carmine, and crimson, are of the same origin. At a later period, kermes was also called coccus scarlatinium, though the time at which it first received this appellation cannot now be accurately ascertained. The term granum was applied to it on account of its resemblance to a grain or berry; and hence colours dyed from this insect were frequently called grain, or engrain colours.

107. When the living insect is bruised, it yields a red colour, the smell of which is not unpleasant. Its taste is bitter, harsh, and pungent. In the dried state, it imparts this smell and taste to water and alcohol, giving to both a deep red colour, which is retained by the extracts made by these infusions.

108. Kermes is one of the most ancient dyes with which we are acquainted, but it has fallen greatly into disuse since the introduction of cochineal. Most of the writers on dyeing admit, that the colour which kermes imparts to wool, is inferior in beauty to the scarlet made with cochineal; Dr Bancroft, however, maintains, that by employing along with it a solution of tin or nitro- muriatic acid, he procured a scarlet in every respect as beautiful and estimable as any which can be dyed with that insect. This statement deserves attention, as the colour communicated by the kermes is more durable, and spots of grease may be discharged from it without injury. Hellot mentions that the red draperies of the figures represented in the ancient Brussels, and other Flemish tapestries, were all dyed from kermes, and that this colour, after having stood more than 200 years, seems to possess the same brilliancy as at first. Bechnam affirms the same thing with respect to some pieces of tapestry supposed to have been dyed with kermes about the twelfth century. Dr Bancroft states, that the decoction of kermes exhibits, in almost every case, the same appearances with the different chemical agents as cochineal: and he has accordingly concluded, that the colour of both is "exactly similar."

109. The coccus polonicus is a small round insect, similar to the kermes, and employed for nearly the same purposes. It is found adhering to the roots of a species of polygono- nium (severanthus perennius). Before the introduction of cochineal caused the use of it to be abandoned in Europe, it was chiefly collected in the Ukraine and other provinces of Poland, under the name Cermès. The juice of the coccus polonicus is still employed as a dye by the Turks and Armenians, particularly for wool, silk, and horse hair. The women also use it to colour their nails.

110. Several other insects might be noticed which afford a red colour, and some of them have been employed for that purpose in Europe; but the advantages offered by cochineal have entirely superseded their use, and caused them to fall into neglect.

111. Lac is a colouring matter, of animal origin, having a colour more or less red. It is produced in the East Indies by the coccus lacca, a small winged insect, and is generally deposited on the small branches of the croton laccaferum. "The fly is nourished by the tree, and there deposits its eggs, which nature has provided with the means of defending from external injury, by a collection of this lac, evidently serving the twofold purpose of a nidus and covering to the ovum and insect in its first stage, and food for the maggot in its more advanced state. The lac is formed into complete cells, finished with as much regularity and art as a honeycomb, but differently arranged. The flies are invited to deposit their eggs on the branches of the tree, by besmearing them with some of the fresh lac, steeped in water, which attracts the fly, and gives a better and a larger crop. The egg, which is about the size of an
112. The cells are filled with a glutinous liquid, which is sweetish to the taste, and of a fine red colour, soluble in water. This liquid is secreted by the insect, and is destined as a food to the embryo, from the time of its animation till able to quit its cell in quest of food. The natives of Assam use it as a dye, and cotton dipped in it makes afterwards a very good red ink. The eggs, and dark coloured glutinous liquid with which they are surrounded, communicate a very beautiful red colour to water while they are fresh; but after they have been dried and kept for some time, the colour they afford is less bright. "It would therefore be well worth while," says Dr Roxburgh, "for those who are situated near places where the lac is plentiful, to try to extract and preserve the colouring principles by such means as would prevent them being injured by keeping. I doubt not," continues he, "but in time a method may be discovered to render this colouring matter as valuable as cochineal."

113. As an article of commerce, lac is known in Europe under the appellations of stick-lac, seed-lac, and shell-lac. The first is the lac in its native state, as it is found adhering to the twigs on which it was originally deposited. The seed-lac is said to be the stick-lac broke into small pieces, and thus appearing in a granulated form. This, however, is a mistake; seed-lac being the yellowish hard resinous powder, which remains after the red colour of stick-lac has been extracted, as far as it can conveniently be done, by water. Shell-lac is produced from seed-lac, by putting the latter into long cylindrical bags of cotton cloth; melting it, by holding the bags over a charcoal fire; and when the lac melts, straining it through the cloth, by twisting the bags. The lac thus strained, is allowed to fall upon the smooth junk of a plantain tree, and is there spread into thin plates. In this form it is brought to Europe, and is chiefly employed in the composition of varnishes and sealing-wax.

114. For the purposes of dyeing, stick-lac of the deepest colour should be chosen. The colour which it affords is less brilliant than the scarlet obtained from cochineal; but it has the advantage of possessing greater durability. Berthollet says, that it may be employed to good purpose by mixing a certain quantity in the cochineal, when, if it be not in too large proportion, the scarlet will be rendered more permanent, without losing any thing of its beauty.

115. Water dissolves lac, and the decoction is of a deep crimson colour. The solubility is increased by alkaline substances. Pure potash and soda completely dissolve the different kinds of lac. Pure ammonia, and carbonate of ammonia, also act on its colouring matter. To separate the part soluble in water, and calculate its proportion to the wax or resin, Hellot used to extract it by means of water and mucilage of comfrey, to precipitate the colouring matter with alum, and to collect and dry this precipitate, the weight of which was only one fifth of the lac. This precipitate is a compound of the colouring matter and alumine: Hellot used it for dyeing.

116. Dr Bancroft seems to be of opinion, that lac employed with the nitro-muriate of tin and tartar, might be made to dye scarlets, equal in vivacity and beauty to any which have been produced from cochineal, and by the same means, taking care only to employ them in a proportion somewhat larger. He ascertained, in the course of his experiments on this substance, that water, at the ordinary temperature of the atmosphere between the tropics, dissolved and extracted almost as much of the colour of powdered stick-lac, as when assisted by a boiling heat. He discovered also, that water of this temperature extracted the colouring matter free from other substances, which were dissolved by it at the boiling point. Having carefully evaporated a few quarts of this cold infusion of powdered stick-lac, made during some warm days in the early part of September, he obtained an extract, which, when dried and rubbed in a mortar, broke readily into fine powder, and was afterwards found to dissolve almost as readily as refined sugar; and having tried this powder to dye small pieces of broad cloth, with the usual mordants, he says he had no difficulty in producing therewith scarlet colours equal to the best which could be any where found, and with little more than half as much in weight of the powder as would have been required of cochineal to produce similar colours. In consequence of these results, and considering the low price of stick-lac in the East Indies, he was convinced that this colouring matter might be successfully introduced as a substitute for cochineal. He accordingly communicated his opinion on the subject to the Chairman of the Court of Directors of the East India Company, and offered to disclose the result of his experiments, for a moderate but suitable remuneration. The Committee of Directors, before coming to a final determination, prudently proposed the dyeing of a piece of long cloth (the woollen cloth of which the Company's exports are chiefly composed,) in order that the practicability of the method might be ascertained on a sufficiently large scale; the samples which Dr Bancroft had produced being taken from small bits of cloth. The first experiment succeeded so well, that the colour produced was approved of by very competent judges; but in some subsequent trials, the results fell short of expectation, the colour being deficient in brightness. When the decoction of the lac began to acquire a little of the consistency of a soft extract, a sudden and remarkable diminution of the beautiful colour of the liquor was observed. The change was ascribed to the absorption of oxygen; Dr Bancroft having noticed a similar effect produced on logwood in the same circumstances. To obviate this inconvenience, he has proposed to obtain the extract by evaporation with the heat of the sun only; but it is extremely doubtful whether the absorption of oxygen from the atmosphere would not take place in an equal degree, during so protracted a mode of extracting the colour. He has also proposed to collect the colouring matter of lac by precipitating it from its aqueous solution by the oxide of tin, and after letting off the superincumbent water, to separate the precipitate from all the remaining moisture, by suspending it in close linen bags, and afterwards drying it in the sun, or even in the shade. One pound of nitrate of tin, in which the acid of the ordinary strength (1.170) was saturated with the metal, appeared capable of precipitating as much of the colouring matter of lac as, in its effects, would be equal to one pound of cochineal. He accordingly attempted to dye a piece of cloth with this precipitate, but owing to deficiency of colouring-matter, and other causes which lie mentions to account for the failure, the experiment was not successful. He still seems to think, however, that in this, or some other
form, lac might be used with considerable advantage as a dye, and even as a substitute for cochineal.

117. We shall conclude this division of adjective colouring matters, with a short account of those properties of Prussian blue which we have not considered under the head of Prussian acid: (See Chemistry, p. 60.) Prussian blue is a triple compound of Prussian acid, an oxide of iron, and potash. The oxide of iron may combine in different proportions with the acid; when it is in excess, the solution is yellowish, but when it is in a proper proportion, it is blue. The excess of the oxide of iron may be taken up by an acid: the muriatic is found to answer the purpose best, and when it is added, the compound becomes of a beautiful blue.

118. An alkali digested on Prussian blue or prussiate of iron, combines with the Prussian acid, and separates the iron from it. The addition of an acid which has a more powerful attraction for the alkali than the Prussiate, detaches the latter from the alkali, and a double play of affinities is brought into action. The acid which is added unites with the alkali, while the Prussian acid forms with the oxide of iron the Prussian blue. At the minimum of oxidation, iron is incapable, in whatever proportion it may be applied, of producing a blue with the Prussiate acid; and hence, if the prussiate of potash be added to a recently prepared sulphate of iron, the precipitate is white, and remains colourless until it absorbs oxygen from the atmosphere. Berthollet supposes that the white prussiate of iron differs from the blue, not because it is less oxygenated, but because the sulphuric acid in the green sulphate of iron adheres more strongly to its basis than when the iron is more highly oxidized; and as a proof of this, he states, that, by adding the muriatic, the sulphuric, or phosphorous acids to the white prussiate, it becomes blue, though none of these acids can afford oxygen.

119. Whatever theoretical opinion may be entertained with respect to the cause of the formation of Prussian blue, the uncommon beauty and lustre of the colour itself have recommended it as a dye, and occasioned various attempts to fix it equally and permanently upon cloth. No method which has hereunto been proposed can be said to have completely answered the purpose; for whatever care has been taken, the colour is frequently weak and dull, and always uneven. Dr Bancroft has indeed described a method, (which we shall afterwards notice,) by which, he says, he was able to obviate the difficulties hitherto attending the use of this colouring matter. Some pieces of cloth so dyed possessed an intensely full colour, and a lustre greatly surpassing every thing before seen in wool, equaling even the transparency and brilliancy of the finest sapphire to such a degree, that the eye which has once seen the Prussian blue so communicatéd, disclaims afterwards to fix itself upon the common indigo blue.

120. The Prussian acid produces coloured compounds with other metallic oxides besides those of iron. The most remarkable, and perhaps the most important of these, is the red prussiate of copper. This colour was obtained by Dr Bancroft from the different solutions of copper in the sulphuric, the nitric, the muriatic, and the acetic acids, and particularly well by that in the volatile alkali. The prussiate of copper is distinguished from the prussiate of iron by its extraordinary permanency; for though all the alkalis readily decompose the Prussian blue, they have no effect upon the combination of the Prussian acid with copper. Such, indeed, is its durability, that neither the acids nor washings with soap, however numerous, nor exposure to the weather for the longest space of time, seem capable, in the least degree, of diminishing either its body or its lustre. Dr Bancroft says, that this colour might prove highly useful, by way of topical application upon cottons, and perhaps in dyeing cotton yarn for stripes of muslins, borders of handkerchiefs, &c.

II. Of Vegetable Adjective Colours.

121. One of the most important colouring matters belonging to this class is madder. This substance is the root of a plant, which Linnaeus divides into two species, the rubia tinctorum folis sents, and the rubia peregrina folis quadrata. The madder, in a state of preparation for dyeing, is distinguished into different sorts: that obtained from the principal roots is called grape madder, and that produced from the stalks, which, by being buried in the earth, are transformed into roots, non grape. When the madder roots are gathered, the latter are separated to form the non grape, together with the fibres of the roots, which do not exceed a certain degree of thickness, and also such as are too thick, and contain much woody matter. The best roots are about the thickness of a goose quill; they are semitransparent, of a reddish colour, with a strong smell, and a smooth bark.

122. If the roots of madder be examined with a microscope, the interior part is observed to contain a considerable proportion of specks of a bright red colour; but the ligneous part which surrounds these, as well as the bark, abounds with a brownish yellow colouring matter, which tends greatly to degrade the red that madder would otherwise afford. The pernicious effects of this yellow matter, when madder is used as a dye, may in some degree be avoided, by extracting the colouring matter in water which is but moderately warm, the yellow matter being but imperfectly dissolved so long as the heat is below the boiling point. The outer bark and ligneous parts are also more easily pounded than the parachymatous parts, to which the red colour is more immediately attached, and, on this account, a separation may, to a certain extent, be effected by mechanical means. This separation is established among the French dyers the distinction of madder into rober, mis-robee, and courte. After the first operation of the mill, the madder is passed through a sieve with a cover fitted to it, and, by this means, what is called the short madder, which is used for inferior colours, is obtained; the remainder being again ground and sifted, produces the mis-robee; and a third operation affords the robee or finest madder.

123. Water of the ordinary temperature of the atmosphere may be made to dissolve almost all the red colouring matter from madder; but for this purpose it must be employed in large quantity; and the colour is more beautiful when the solution is obtained by cold than by hot water. Alkalies increase the dissolving power of water, particularly with respect to the yellow matter. The residuum is very inconsiderable, so that madder appears to consist almost wholly of colouring matter. The latter portions of the extract, which seems to be chiefly yielded by the ligneous and cortical parts, is fawn-coloured.

124. The red colouring matter of madder is soluble in alcohol, and, on evaporation, a deep red residuum is

* Except the oxymuriatic, which decomposes it.
DYEING.

125. D'Ambourney and some others pretend, that the roots of madder may be used with greater advantage when they are freshly gathered, than after they have been kept for some time, and reduced to the state of powder. This assertion, however, is by no means countenanced by the general experience of practical dyers, who find, that, if properly dried, and carefully preserved from moisture, madder improves by keeping, at least during the two first years.

Chay. Yields a colour inferior to madder.

126. The colour yielded by the chay, chayuver of the Tamula, which Dr Roxburgh has ascertained to be a species of oldelandia, is nearly allied to that of madder. This plant is a small biennial, rarely a triennial, growing spontaneously on light sandy soils, and extensively cultivated on the Coromandel coast. The cultivated roots are very slender, and from one to two feet in length; the wild are shorter, and yield more colouring matter, which is also of a superior quality. The colour, which is of an orange hue, seems to reside almost entirely in the bark of the roots.

127. The chay root is said to be extensively employed as a dye in India; but the colours obtained from it, by those who have examined its properties in this country, do not warrant us to recommend its importation. Dr Bancroft states, that the best specimens of it which he could procure, did not seem, in any instance, to yield a colour superior to that of madder, but, in general, greatly inferior both in beauty and durability. With the solutions of tin, it produced a very bright and lasting red on wool; though, like that of madder, it inclined too much to the orange. With the oxides of iron it produced nothing darker than drab colours, either upon wool or cotton. Broad cloth dyed without any basis, acquired from chay root a brownish red, which was neither so bright nor so durable as that which it assumes in the same way from madder.

128. The colouring matter yielded by the roots of galium, a genus of plants belonging to the same order as the preceding, differs but little from that of madder; only when the brown external covering of the root is removed, the colour which it imparts to wool is somewhat brighter, with an aluminium basis. The several species of galium chiefly employed in dyeing, are the following: Galium tinctorium, galium verum, galium mollugo, galium sylvaticum, galium boreale, galium aparine. The galium tinctorium is found in great abundance in the woods of North America, and its roots are employed by the native inhabitants to dye porcupine quills of a red colour. The galium verum, yellow ladies' bed-straw, or cheese remaining, affords a colour which is but little inferior to the scarlets dyed with cochineal. The roots, which afford the colouring matter, are covered by a very dark bark, which must be removed, to prevent its affecting the colour of the rest of the root. The dye thus obtained is employed by the people of the Highlands, and of some of the islands of Scotland, for giving a bright red to their woollen stuffs. The galium mollugo and the galium sylvaticum, yield a colour equally bright and lasting. The galium boreale is said to afford a more brilliant red than any other species. Its roots are used as a dye by the inhabitants of Switzerland. The galium aparine, common rough ladies bed-straw, cleaners, or goose grass, also affords a red dye, but inferior to the last. Dr Bancroft has noticed a variety of other colouring matters nearly allied to madder, but their properties are too unimportant to merit consideration in this work; we shall therefore now proceed to make some observations on Brazil wood.

129. Brazil wood, as an article used in dyeing, is the heart, or central part, of a large tree which grows in Brazil. Berthollet states, that it derives its name from that part of South America; but Dr Bancroft has decidedly proved, that the country took its name from the wood, not the wood from the country. Brazil wood is mentioned in some old charters, particularly one dated in 1398, and another in 1306, under the name of Brazilis, which, as well as Brasilia, is understood to be derived from Brazilis, a burning coal, to denote its fiery red, or flame colour. It is also called Farnambucca, wood of St Martha, of Japan; and of Sans. Linnaeus describes the tree which furnishes Brazil wood under the name Cassapina crista; which gives the Japan or sappan wood, by the name Cassapina sappan; and that of Antilles, which is the least esteemed, he calls Cassapina vesicaria. That which comes from Farnambucca is the most valuable.

130. Brazil wood is very hard, and takes a good polish. It is pale when first cut, but reddens by exposure to the air. It sinks in water, and its goodness is known by its weight. Boiling water extracts the whole of its colouring matter, and becomes of a fine red if the boiling be continued sufficiently long. A black residue remains, which still yields much colouring matter to alkalis. A more perfect solution is obtained by alcohol, and also by ammonia; at least the colour is deeper. The practice of sprinkling the powder of Brazil wood, during the operation of grinding it, with starch, probably raises the colour, by means of the volatile alkali which it contains.

131. Fresh decoction of Brazil wood yields, by the addition of sulphuric acid, a small quantity of a red precipitate, inclining to fawn colour; the liquor remains yellow and transparent. Nitric acid renders the liquor yellow at first; but if more be added, the liquor acquires a deep orange colour, and becomes transparent, after having deposited a precipitate nearly resembling the former in colour, but more copious. Muriaic acid produces the same effects as the sulphuric. Oxalic acid produces a precipitate of an orange red, nearly as copious as the nitric acid does. The liquor remains transparent, and of the same colour as in the former trials. Distilled vinegar gives a very little precipitate of the same colour: the liquor remaining transparent, and a little more inclining to orange. Tartar furnishes still less precipitate, and leaves the liquor turbid. Fixed alkali restores the decoction to a crimson, or deep violet inclining to brown. Ammonic gives a brighter purple, or violet, and a little precipitate of a fine purple. Alum occasions a red precipitate inclining to crimson: the liquor also affords a copious precipitate on saturating the acid of the alum with alkali. In this way an
extracting the colour of red saunders by alcohol, he
communicated to wool a colour almost equal to scarlet.
A very bright and lasting orange may be given to
broad-cloth, prepared, as usual, with alum and tartar,
by employing equal portions of ground sumach and
red saunders.

137. The wood of the Hematoxylon Campechianum
affords a colouring matter, which is used very exten-
sively in dyeing. In commerce, it is known by
the name of logwood, and also of India or Campeachy
wood. Logwood is so heavy as to sink in water; it
possesses great hardness, and, by the compactness
of its grain, takes a fine polish. Its prevailing colour
is brown, tinged with shades of orange, yellow, and
brownish black, and is extracted in the same manner as that of
Brazil-wood. Six quarts of distilled boiling water are
capable of extracting almost all the colouring matter
of one pound of logwood properly chopped. The
decotion is of a yellow colour, and has a sweetish taste.
If the decoction be made with common water, it ex-
hibits a full red, or dark blood colour, probably by the
action of the calcareous earth which common water
usually contains in combination with it; but by adding
to it sulphuric, nitric, or muriatic acid, the yellow is
restored.

138. When logwood is of a good quality, it yields
from one-fifteenth to one-twentieth of its weight of
pure colouring matter, soluble in water and in alcohol,
if the decoction after being obtained has been speedily
evaporated to dryness; but if an interval of several
weeks has been allowed to intervene, or if the evapo-
ration has been conducted slowly, and the decoction
has been exposed to the sun and air, the colouring mat-
terial will absorb a large quantity of oxygen from the
atmosphere, and become nearly insoluble in water,
while the colours dyed from it will be more fugitive
than those produced by a decoction recently prepared.
In this respect it differs greatly from Brazil wood.

139. Chips of logwood being boiled in water acidulat-
ed with sulphuric acid, afford a brownish yellow deco-
cion, which communicates to wool a strong yellowish
bright snuff colour, of considerable durability. Nitric
acid being mixed with a decoction of logwood, produces a
fine bright yellow, which becomes a yellowish brown
by boiling, and imparts the same colour to wool. Cloth
boiled with a decoction of logwood, slightly acidulated
by muriatic acid, takes a brownish yellow colour.
If a sufficient quantity of alum be added to a decoction
of logwood, the colouring matter is all precipitated in
combination with the alumine, of a purple or reddish
violet colour. A sulphate of iron occasions a copious
bluish black precipitate. All the solutions of tin pro-
duce purple or violet colours, and a complete precipi-
tation of the colouring matter. Sulphate of copper gives
a purplish blue colour; sulphate of pure zinc, a dark
purple; muriate of mercury, an orange red; muriate
of antimony, a beautiful crimson; acetate of lead, a
black precipitate, with a slight tinge of red; muriate
of laries, a reddish purple; muriate of magnesia, a
yellow; sulphate of lime, a purple; arseniate of pot-
ash, a deep yellow.

140. The best and most permanent of the purple or
violet colours obtained from logwood, are produced
by mordants, principally composed of the solutions of
tin. In another part of this article, we shall describe
the process employed for dyeing in this way upon wool,
a colour which was very fashionable in France, upwards
of thirty years ago, under the name of Prune de Mon-
sieur. Wool dyed with logwood, and either sulphate

DYEING.
of copper or verdigris, acquires a blue colour, of little brightness and durability, which is chiefly recommended by its cheapness. The high price of indigo has of late rendered this mode of dyeing blue very general, particularly in France.

141. The principal consumption of logwood is for blacks, to which it gives a lustre and velvety cast, and for greys of certain shades. It is also employed very extensively for different compound colours, which it would be difficult to obtain of equal beauty and variety, from colouring matters of a more permanent nature. It is frequently mixed with Brazil wood, to render colours deeper, the proportion of the two woods being varied according to the shade desired. In short, no colouring matter with which we are acquainted, is capable of affording so great a variety of dyes, though this advantage is much diminished by their want of permanency.

Quercitron.

142. The bark of the quercus nigra of Linnaeus affords a yellow dye, which is at present very generally employed. This substance was first prepared as a dye by Dr Bancroft; he having given it the name of quercitron, by which it is now universally recognized. "The bark of the quercus nigra appears," according to his account, "to consist of three parts or coats. 1st, The epidermis, or external coat, through which the several excretions of the tree are transmitted, which, in part at least, adhere to its outer surface, and become almost black by condensation. 2d, The middle or cellular coat, in which the colouring matter principally resides. 3d, The interior or cortical part, consisting chiefly of lamina, formed by the reunion of different vessels, which become more hard and fibrous as they are placed nearest to the woody part of the tree, and have therefore less room to contain the colouring matter."

143. Before extracting the colour from the bark, the epidermis, or external covering, ought to be removed, by shaving. The remaining parts being then properly ground by mill-stones, separate partly into a light fine powder, and partly into stringy filaments or fibres, which last yield but about half as much colour as the powder, and therefore care should be always taken to employ both together, and as nearly as possible in their natural proportions, otherwise the quantity of colour produced may either greatly exceed or fall short of what is expected. The querciton bark thus prepared and proportioned, says Dr Bancroft, will generally yield as much colour as eight or ten times its weight of the weld plant, and about four times as much as its weight of the chipped old rustic. The colouring matter, continues he, most nearly resembles that of the weld plant, with this advantage, however, that it is capable alone of producing more cheaply all, or very nearly all, the effects of every other yellow dyeing drug; and, moreover, some effects which are not attainable by any other means yet known.

144. The colouring matter of quercitron readily dissolves in water, even at a blood heat. If the infusion be strained and left at rest, a quantity of resinous matter settles in the form of a whitish powder, which produces the same effects in dyeing as the part remaining in solution. The clear effusion being evaporated and dried, affords an extract equal in weight to about one twelfth of the bark from which it was obtained. Much care, however, must be employed in procuring this extract, so as to make it produce colours equal in beauty to those obtained directly from the bark itself. If the evaporation be carried on rapidly, and the heat be too great, the colour is tarnished, probably, as Dr Bancroft conjectures, from the absorption of oxygen, the colour thus undergoing a sort of semi-combustion. On the other hand, if the evaporation be conducted too slowly, the colouring matter suffers another change, and soon spoils by keeping.

145. The decoction of quercitron is of a yellowish brown colour, which is darkened by alkalis, and brightened by acids. A solution of alum being added to it, separates a small portion of the colouring matter, which subsides in the form of a deep yellow precipitate. The solutions of tin produce a more copious precipitate, and of a beautiful lively yellow colour. Sulphate of iron causes a copious olive precipitate; sulphate of copper, a yellow of an olive cast.

146. The weld plant, (Reseda luteola,) seems to have been employed from the remotest times as a yellow dye. Two sorts of it are distinguished, the cultivated and the wild; the former is preferred, as it yields more colouring matter. The wild species differs from the cultivated, in producing taller and stronger stalks. The whole of the plant is used in dyeing.

147. A strong decoction of weld is of a yellow colour, Properties inclining to brown; if it be greatly diluted with water, of the det- sits yellow, which is more or less pale, has a greenish tinge. The addition of an alkali deepens the colour of the decoction, and after a certain time a little ash-coloured precipitate is thrown down, which is insoluble in alkalis. The action of the alkali renders its colour paler, and produce a little precipitate which dissolves in alkalis, and gives them a yellowish brown colour. Alum occasions a yellowish precipitate, and the liquor retains a fine lemon colour. The solutions of tin produce a copious bright yellow precipitate. Sulphate of iron produces a copious dark grey precipitate, and the supernatant liquor is brownish. Sulphate of copper causes a brownish green precipitate, and the liquors preserve a pale green colour.

148. To extract the colour of weld for dyeing the plant is boiled in a fresh bath, inclosing it in a bag of thin linen, and keeping it from rising to the top by means of a heavy wooden cross. Some dyers continue the boiling till it sinks to the bottom of the copper, and then let a cross down upon it; others when it is boiled, take it out with a rake, and throw it away. The decoction should be employed as soon as possible after it has been prepared, as it soon suffers a decomposition, which renders it useless.

149. Common salt added to the weld bath, renders its colour richer and deeper; sulphate of lime or gypsum also deepens it. Alum renders it paler, but more lively; and tartar still paler. Sulphate of iron makes it incline to brown. The shades obtained from weld may be modified, with these additions, by the proportion of the weld, by the length of the operation, and by the mordants employed in preparing the stuff. The colour may be modified also by passing the cloth, when it is taken out of the bath, through other dyes.

150. Dr Bancroft has stated several objections to the use of weld, compared with quercitron, as a dye. When compared with those of querciton it is nearly, if not wholly, free from these defects. It is obvious, however, that, in many cases, these qualities must recommend the use of weld.
DYEING.

231

Adjective Colouring Matters.

Fustic.

Properties of the decoction.

151. Fustic, the wood of the morus tinctoria, a tree of considerable size, which grows in various parts of the West Indies, affords a yellow colouring matter, which is very extensively used in dyeing. The colour which it yields is neither high nor bright, but it possesses considerable durability, and is less affected by acids than the quercitron and weld yellows. Fustic abounds much in colouring particles, though in this respect it is greatly inferior to quercitron, as it only affords one-fourth the quantity of colouring matter.

152. A strong decoction of fustic is of deep reddish yellow colour, which becomes an orange yellow when diluted with water. The greater number of the acids render this liquor turbid; a small quantity of a greenish yellow precipitate is formed, and the supernatant liquor is of a pale yellow. Alkalies redissolve the precipitate, and give the liquor a deep reddish colour. Alum forms a small precipitate of a yellow colour; alum and tartar a like precipitate. Muriate of soda makes the liquor a little more deeply coloured, without producing any precipitate. Sulphate of iron forms a precipitate, which is at first yellow, but afterwards becomes more and more brown. Sulphate yields a copious brownish yellow precipitate. Fustic and weld are sometimes used together, in quantities proportioned to the desired effect. Fustic is also very commonly employed with the sulphate of indigo, in dyeing Saxon greens upon cloth.

153. Fustic, as well as many other woods which yield a yellow colour, contains a quantity of resinous and extractive matter in combination with a portion of tannin. This last principle diminishes the brilliancy of the yellow afforded by fustic; but Chaptal has proposed an easy method of detaching it from the colouring matter, though it may affect its durability. The method to which we allude, is founded upon the attraction of tannin for glue. He accordingly recommends that animal substances, containing gelatinous matter, such as bits of leather, glue, &c. should be added to the decoctions of fustic. This process precipitates the tannin, and enables the colour to exhibit greater brilliancy.

154. Venice sumach, the wood of the rhoe cotinus, a shrub growing principally in Italy, and the South of France, affords a full high yellow of little durability. Dr Bancroft, indeed, mentions that this defect may, in a great degree, be remedied, by employing tartar, along with the muriate of tin, the mordant by means of which this colouring matter is usually fixed. Four pounds of the rhoe cotinus chipped, afford no more colour than one pound of quercitron. It is frequently mixed with other colouring substances, particularly cochineal, to give a fine colour to scarlet; also for pomegranates, oranges, jonquilles, gold colours, buff, and in general for all those colours which it is wished should have an orange cast.

155. Common sumach, (rhoe cotinum,) a shrub, growing naturally in Syria, Palestine, Spain, Portugal, and some parts of North America, yields a pale yellow dye, with the aluminous basis. The infusion, which is obtained from the wood previously reduced to powder by a mill, is of a greenish fawn colour, but it soon becomes brown by exposure to the air.

156. A solution of potash produces very little change on it, while recent; acids brighten its colour, and turn it yellow. A solution of alum renders it turbid, and produces a small yellow precipitate. Of all astringents, sumach bears the greatest resemblance to galls. The precipitate which it produces with solutions of iron is less in quantity than what is obtained by an equal weight of galls, but it is very copious, and may be substituted for them by increasing the quantity.

157. Sumach alone gives a lawn colour inclining to green; but cotton stuffs, which have been impregnated with the acetate of alum, take from it a very good durable yellow. It is principally employed for drab and dove colours in calico printing, and for dyeing black with iron, and the solutions of that metal.

158. The berries of the rhoeus cotinaria give a yellow dye, but one which is destitute of durability. They are chiefly used for topical dyeing, in calico printing. The colour which they communicate is so very fugitive, that the practice of dyeing from them should be abandoned.

159. Saw-wort, serrulata tinctoria, affords a better dye, and may be used as a substitute for weld with the aluminous basis. It yields a bright lemon yellow of considerable permanency, which may be heightened with the nitromuriate of tin and tartar.

CHAP. IV.

Of the Durability of Colours.

160. In the view which we have hitherto taken of colouring matters, we have considered the mechanical methods by which they are separated from the substances with which they exist in a state of combination, and the general appearances which they exhibit with a variety of chemical agents. In describing these appearances, we treated them rather as modifications produced upon the original colouring matters, than as actual changes effected in their composition. It must be evident, however, that, from the nature of the chemical agents to which, in some instances, the colouring matters were submitted, decompositions must have taken place, and new compounds been formed; and that these compounds must be more or less durable in proportion as they are capable of resisting the action of the substances to which they are afterwards to be most frequently exposed, viz. light, air, water, acids, alkalies, and soap.

161. The influence of light upon colouring matters has been long known; but it was reserved for the delicate precision of modern analysis to discover the mode of its operation. To do this, a knowledge of the composition of light itself, the most subtle of all material substances, was no less necessary than an acquaintance with the constitution of coloured bodies. Without entering into any detail on this subject, it will be sufficient to state the results which have been obtained by experiment.

162. Light appears to consist of three kind of rays, which form one homogeneous compound in the solar beam. These have been termed calorific, colorific, and deaquilizing rays: (See Chemistry, p. 32.) It is the nature of the latter which we propose to consider more particularly at present. The deaquilizing rays exert their agency chiefly in occasioning decomposition. The element which they most frequently detach from a state of combination with other bodies, is oxygen; and from this property, indeed, they derive their name. Colourless nitric acid exposed to the rays of the sun soon becomes red and fuming, a state which is known to proceed from a partial separation of its oxygen. Oxy-

The influence of light in evolving oxygen is equally demonstrated by this experiment, whether we retain the old opinion respecting this gas, or adopt the hypothesis of Sir Humphry Davy.
Dyeing.

165. It appears, that, in some cases, the absorption of oxygen by the colouring matter produces a change of colour, in consequence of the oxygen combining with the hydrogen, and thus forming water; so that the change which takes place is rather to be ascribed to the separation of hydrogen, than to the permanent union of the oxygen with the colouring particles. Berthollet observed, that the oxyymuriatic acid exhibited different phenomena with the colouring matter; that sometimes it discharged their colour and rendered them white; that most frequently they changed to a yellow, fawn colour, brown, or black, according to the intensity of its action; and that, when their colour appeared only discharged or rendered white, heat, or a length of time, was capable of rendering them yellow. He concluded, that the effects of the oxyymuriatic acid were similar to those of carbonization, occasioning a destruction of the hydrogen, which, combining with the oxygen more easily, and at a lower temperature than charcoal does, leaves the latter predominant; so that the natural colour of charcoal is more or less blended with the original colour.

166. From what has been stated, it appears, that changes may be produced in the colours of bodies, either by the separation of oxygen, or by the union of that principle with one of the elements of the colouring matter. In the latter case, which applies chiefly to vegetable substances, the oxygen combines with the hydrogen; the attraction of the colouring particles for their basis is thus weakened, and they are easily carried off by water. This effect takes place more or less rapidly, according to the nature of the colouring particles, or rather, according to the properties which they possess in the state of combination into which they have entered. Colouring substances, therefore, resist the action of the air the less they are disposed to unite with oxygen, and thereby to suffer, more or less quickly, a smaller or a greater degree of combustion. Light promotes this effect, which, in many cases, is not produced without its assistance; but the colouring matter, in its separate state, is more liable to suffer this combustion than when united to a substance such as alumine, which may either defend it by its own power of resisting combustion, or, by attracting it strongly, weaken its action on other substances, which is the chief effect of mordants; and, finally, this last compound acquires still greater durability when it is capable of combining intimately with the stuff.

167. Dr Bancroft has stated several objections to this theory, some of which appear to possess considerable weight, while others are founded upon limited views of the subject. Berthollet has stated, that, in consequence of oxygen combining with the hydrogen of colouring matter, the charcoal becomes predominant, and manifests its presence by the brownish appearance which the colouring matter exhibits. Dr Bancroft seems to conceive, that this explanation implied, that charcoal existed in vegetable matters in the same state in which it is found in charred wood, and that it was naturally of a black colour; but this supposition is by no means necessary for the truth of the theory. It is a certain fact, that in whatever way the carbonization of vegetable matter is effected, the charcoal obtained is always of a dark colour; this is the case, whether the vegetable matter be subjected to combustion in close vessels, or placed in a situation (under water, for example) where the volatile matters either make their escape, or unite with the bodies with which they are in contact. The charcoal thus obtained, may not have the same state in the vegetable substance from which it has been procured; and, indeed, there is every reason to conclude, that charcoal is a combination of oxygen and pure carbon; but, at any rate, it is enough for M. Berthollet to state, in support of his opinion, that in all cases when the volatile parts of vegetable matter have made their escape, the carbonaceous part which remains behind is black. We conceive, therefore, that Dr Bancroft has done nothing to disprove the correctness of Berthollet's opinion, by simply maintaining, that "he should never be convinced that these matters had originally contained ready formed black charcoal, and that the degradation of the faded or injured colour, resulted from a greater manifestation, and pre-
Durability of Colours.

Oxymuriatic acid used as a test of the durability of colour.

169. "When, therefore, we wish," continues he, "to compare together two or more colouring substances of the same nature, and to determine the relative quality and quantity of the colouring particles in each, we need only compare the quantities of the same oxygenated muriatic acid required to produce the same degree of deterioration in an equal weight of each; the qualities of these substances, or the quantity of colouring particles they contain, are directly proportionate to the quantities of liquor required to produce the same effect on each; but, in this experiment, it is necessary that the colouring matter of each substance should have been dissolved in a proper liquor, and that all the circumstances in the process of comparison should be similar. If we wish, for example, to compare several kinds of indigo, we take an equal weight of each, powder them carefully, and mix them into separate matrices. With eight times their weight of concentrated sulphuric acid: These are to be kept for twenty-four hours, in a heat of from 30° to 40° (86° to 104° of Fahrenheit). Each solution is then to be diluted with a quantity of water, filtered, and the residue found on the filters to be collected, and ground in a glass mortar, and again digested with the addition of a little more sulphuric acid: the last solutions are also diluted with equal quantities of water, filtered, and each added to its corresponding liquor. Finally, to each solution is added as much oxygenated muriatic acid as will discharge the colour, or rather bring them all to the same shade of yellow. The qualities of the different kinds of indigo, are proportionate to the quantities of oxygenated muriatic acid required to destroy their colour. The proofs of such colouring particles as are soluble in water, are much more simple: it is only requisite, after having extracted them as much as possible, to mix oxygenated muriatic acid with equal bulbs of the juice, of the same weight of each substance, and to compare the quantity of acid required to bring them all to the same hue."

VOL. VIII. PART I.

170. Though we are inclined to adopt the general principles of Berthollet's theory, and to admit, that the oxygen of the atmosphere and the oxymuriatic acid act upon colouring matters in a manner somewhat similar, we are not disposed to believe, with this eminent chemist, that the mode of action in the two cases is exactly alike, or, that the effects produced by the one afford a precise criterion of the nature of the operation of the other. Dr Bancroft has very justly remarked, that the properties of oxygen are greatly diversified by its union with other bodies; and that, in selecting the oxymuriatic acid as an accurate test of the changes which colouring matters suffer from exposure to the air, Berthollet entirely overlooked the action of the basis with which the oxygen is united; though there cannot be a doubt, that so powerful an agent as the muriatic acid must greatly modify the effects of the oxygen. Dr Bancroft mentions several experiments which add considerable weight to his objections, and, at least, prove, that the oxymuriatic acid cannot, in all cases, be considered as an accurate test of the durability of colour. He put into a small phial cuttings from three skins of cotton yarn, which had been dyed and sent to him by Chaptal. One of these had received the Turkey red, another the Nankeen buff from an oxide of iron, and the third a black from madder and galls, as he supposed, applied upon the basis of iron dissolved by the pyrogallol. "Unhappy," says he, "I poured oxymuriatic acid, which had been prepared by Mr Accoum, and kept secluded from light. Its acidity was so slight as to be hardly perceptible to the taste, and, I believe, it might have been put into the eye without occasioning much pain. I found, however, that in less than two minutes the colour of the Turkey red was much impaired, and, in five, the yarn throughout the greater part of its surface had become while, without passing through any intermediate colour; and, at the end of half an hour, but a very few sparks of red, less than a pin's head, were perceptible. The buff colour, at that time, was found to have acquired a little body, and the black to have lost a little, but without ceasing to be still a good black. At the same time, I put other cuttings of the same colours into another phial, and poured upon them undiluted aquafortis as prepared for the scarlet dyers; and I found, that, in a single minute, the black, which had withstood the oxymuriatic acid, was changed to a buff colour, resulting solely from the ferruginous basis with which it had been dyed; and the Turkey red began to exhibit the appearance of a scarlet, inclining to the orange; and this last (of a lively tint) became apparently its settled colour at the end of an hour, when the buff, by acquiring more oxygen, was considerably raised. Here, then, was a very great diversity between the effect of the nitric and the oxymuriatic acids, in no degree according or proportionate to their degrees of acidity; that of the nitric acid being at least fifty, and perhaps one hundred times greater than that of the oxymuriatic acid, (which being tasted at the time when its action upon the Turkey red was strongest, and when, according to Davy's opinion, it must have already decomposed water, had not, to my taste, acquired any greater degree of acidity); and yet the former could only change the complexion of the Turkey red to a bright orange, (probably by imparting oxygen to it,) whilst the latter (not, as I conceive, by any such, or other addition, but by a complete decomposition,) had at once annihilated all the colour (leaving the cotton yarn white) as fast and as far, as the decomposition took.
DYEING.

Dyeing of Colours.

place; and this without any intermediate tint, which would not have been the case, if the effect of the oxymuriatic acid had, as M. Berthollet supposes, resembled combustion. And, on the other hand, the black, on which the oxymuriatic acid could make but a very slight impression, was completely destroyed (excepting the colour of its ferruginous basis) by the nitric acid. Dr Bancroft accordingly infers, that the powerful action exerted by the oxymuriatic acid on colouring matters, does not result from the abstraction of its oxygen, but from some quality peculiar to itself; "from the combined agency of its constituent parts, and not from the action of either separately, as has been supposed."

It is obvious, however, that, in reasoning concerning the effects of the nitric and oxymuriatic acids, the Doctor has confounded two things which are perfectly distinct: the acidity of these bodies, and their disposition to part with their oxygen. Even admitting that the quantity of oxygen contained in acid bodies was proportional to their acidity, it would not follow, that the most acid substances would most readily impart their oxygen to other bodies. The nitrous oxide supports combustion with a brilliancy little inferior to oxygen gas itself; the nitric oxide, which, with the same base, contains double the quantity of oxygen, so far from supporting combustion, immediately extinguishes the greater number of burning bodies which are plunged into it. It cannot be inferred, therefore, that, because nitric acid possesses greater acidity than oxymuriatic acid, the former must necessarily give out more oxygen than the latter, to the substances brought within the spheres of their activity. But though this argument is by no means conclusive with respect to the dissimilarity of effect produced by atmospheric air and oxymuriatic acid, and though several explanations might be offered to account for the different results obtained in the preceding experiments, in perfect consistency with Berthollet's theory, the following facts, which Dr Bancroft has stated, certainly tend to prove, that whatever analogy may hold between the action of common air and oxymuriatic acid, the latter cannot be regarded, in all cases, as a measure or indication of what colours would suffer by exposure to sun and air.

172. He put into an empty glass-stopped phial, the following colours upon separate bits of muslin, viz.:--

"1st. A fast madder-red, dyed topically by an eminent calico printer, upon a basis, from acetate of alumine applied by the block.

"2d. A fast yellow, dyed from weld upon the same basis, by the same calico printer.

"3d. A fast yellow, dyed upon the same basis, from quercitron bark.

"4th. A fine durable purple, produced by the colouring matter of the buccinum lapillus.

"5th. A logwood purple, produced by mixing with a strong decocation of that wood as much muriate of tin as rendered the former slightly acid, and, after thickening the mixture with gum-arabic, applying it in spots to muslin; which, after being properly dried, was washed with soap and water.

"6th. A full bright yellow, produced from a similar decoction of the quercitron bark rendered slightly acid by an admixture of nitro-muriate of tin, made with two parts of nitric to one part of muriatic acid; gummed and topically applied in the same manner as the logwood purple, and in like manner dried, and afterwards washed.

"7th. A similar yellow, made from the quercitron bark, only substituting muri-sulphate of tin for the nitro-muriate."

173. "Upon these colours," says Dr Bancroft, "I poured oxymuriatic acid, with which Mr Accam had recently supplied me, (and which I had kept secluded from the light) until the phial was full; after which, in less than two minutes, I found that the bits of muslin, with the madder, weld, and quercitron colours, dyed upon the aluminous basis, were become perfectly white, by a complete extinction of their several colours. Whilst the logwood purple, that from the buccinum, and the quercitron yellows, with solutions of tin, were not apparently changed. But, in about five minutes, the logwood purple appeared to be losing body, as did the quercitron yellows soon after; and a similar effect soon became evident in the shell purple. In about fifteen minutes from the time when these colours were immersed in the oxymuriatic acid, the logwood purple had nearly disappeared; and this was the case of the quercitron yellows in about three minutes afterwards, and of the shell purple about two minutes later; excepting the red spot of the latter, as well as a part of one of the yellows given with tin, had each preserved a portion of colour, by having been protected by the bits of muslin from the sun's rays, which, as the sky was clear, had had free access to the phial containing them at the window where this experiment was made; a fact which manifested the influence of solar light in promoting the destructive action of the oxymuriatic acid on the colours in question. It is here to be recollected," continues he, "that the three first-mentioned colours, dyed upon the aluminous basis, would have resisted the action of sun and air for two or three months, and the madder for a much longer time; and yet they were completely destroyed in an eighth part of the time which was required to destroy the logwood purple, and the yellows with tin; neither of which could have been exposed to the sun and air for a single week without becoming of a faded brown. It is also worthy of observation, that the Tyrian or shell purple was destroyed by the oxymuriatic acid almost as soon as the logwood purple and quercitron yellows last mentioned, though it would have resisted the sun and air probably fifty times longer than either of them." These experiments certainly show, that whatever similarity may subsist between the effects of oxymuriatic acid and atmospheric air on colouring matters, the former cannot be regarded as the very accurate test of the durability of colours, which Berthollet was disposed to represent it. Indeed, the only sure mode of determining the durability of colours, appears to be direct exposure to air, sun, water, and the other agents to which dyed stuffs are most frequently exposed. We shall therefore subjoin the observations of Hellot on this subject, together with his account of the methods employed by Dufay, which laid the foundation of the regulations adopted by the French government respecting fading and durable colours: "The late Mr Dufay," says Hellot, "who had been selected by government as a person whose labours might greatly improve the art of dyeing; made experiments on the subject, by dyeing woof of all colours, and even with dyes of all sorts, used either for durable or fading colours; he even sent to the different provinces for such as are not employed at Paris; and, finally, he collected most of the different substances which he conceived might be employed in the art, and tried a very great number of them, investigating their good or bad qualities, without paying any regard to the prejudices of the dyers.
235

DYEING.

174. With a view to know what colours were, and what were not durable and fading, he exposed to the sun and air, for twelve days, some patterns of all colours, which had been dyed in his own house with known compositions. It appears, that this time was sufficient for a trial of them; for the durable colours are not at all, or but little injured, while the fading ones are almost entirely obliterated; so that, after twelve days exposure to the heat of the sun, and the dampness of the night air in summer, there can be no doubt as to the class in which each colour should be placed.

175. But there still remains a difficulty, which was that the three colours had not been exposed to the air precisely at the same time and in the same season, some might have had more sun, and, consequently, might have suffered a greater change in the twelve days, than others exposed in more cloudy weather, or when the days were shorter. But he discovered a remedy for this inconvenience, which removed all difficulty and doubt as to the accuracy of the experiments; he chose one of the worst colours, that is, one on which the sun had produced the greatest effect in twelve days. This colour served as a standard in the experiments; and whenever he exposed patterns to the air, he always exposed a piece of the stuff along with them; so that he did not calculate by the number of days, but by the colour of his standard, always keeping the pattern exposed, till it had lost as much as that would have done by twelve days exposure in summer. As he always noted the day on which he exposed his patterns, he was led to observe, that in winter it was only necessary to leave them four or five days longer exposed to the air than in summer. By pursuing this method, he removed all doubt as to the accuracy of his experiments. In this trial, by exposure to the air and to the rays of the sun, he had a still farther object, which was, to find the proper proof for each colour. What is called proof, is the trial of a stuff, with a view to discover whether its dye be permanent or not: a pattern is boiled with alum, tartar, soap, vinegar, lemon juice, &c. and its quality is judged of by the effect these substances produce. The proofs used in 1733 were so insufficient, that they did not even assist Mr Du Fay in discovering more certain ones; they even destroyed some good colours, while they produced very little effect upon the bad; so that he was obliged to fix upon several, each of which serves for a great number of colours. The following is a short description of the method he pursued in order to discover them.

176. After having observed the effect of air on each colour, whether good or bad, he tried the same stuff with different furs, and stopped when he found one which produced the same effect with the air; then noting the weight of the ingredients, the quantity of the water, and the length of the trial, he was sure to be able to produce on a colour an effect equal to that which the air would have produced, supposing it had been dyed in the same way with his; that is, according to the methods employed by the dyers of true and false colours. Having thus examined all the colours, and all the ingredients employed in dyeing, he found out a method, which may be considered as accurate, of distinguishing the good or bad qualities of each colour, by making, by means of the proof, a sort of analysis of the materials which composed it. We cannot, without injustice, refuse to acknowledge, that the means Mr Du Fay employed, in the discovery of these proofs, or tests for colour, are ingenious; for the trial by air and sun cannot be made on those, where it is necessary to judge immediately, whether a stuff exposed to sale, at a fair or elsewhere, as if a true dye, be really so or not.

177. The proofs mentioned in the new regulations, made in consequence of Mr Du Fay's memoirs, discharges in a few minutes as much of a colour, where it is not dyed of a durable colour, as would be lost by twelve or fifteen days exposure to the air. But, as general rules for such trials must be liable to many exceptions, which either cannot be foreseen, or, though foreseen, cannot be particularized, without the risk of occasional disputes, it follows, that these rules, considered perhaps as too general, are also too severe in many cases wherein light colours require salts, or quantities of salts, which shall be less active than those necessary for deep or loaded colours, which may allow a considerable portion of their colouring matter to be carried off by a proof, without shewing a very visible alteration. It would, therefore, have been very necessary to prescribe a proof for almost every shade, which, from their infinite variety, would be impossible. Thus the air and the sun will always be the true test; and every colour which is not changed by them in a certain length of time, or which, by exposure, acquires what the dyers call a body, ought to be considered as a standing colour, even though it should be considerably changed by the proofs. Of this we have an example in scarlet; as soap almost entirely discharges this colour, it has been submitted to the trial by alum; and when it has been dyed with cochineal alone, without any mixture of other ingredients, it ought to assume a purple colour in a boiling solution of alum. If scarlet be exposed to the sun, it loses some of its brightness, and becomes deeper; but this deep shade is not similar to that imparted by alum. Proofs, then, in certain cases, cannot be substituted for the action of the air and sun, at least so far as respects similarity of effect.

178. By means of Brazil wood, which, like almost all the other woods loaded with colour, gives a fading dye. I prepared a red which was much finer than the madder reds, and as bright as those made with kermes; this red remained exposed to the air for the two last months of the year 1740, which were very rainy, and for the two first of 1741; notwithstanding the rain and bad weather, it stood, upon account of its peculiar preparation, which will be mentioned in the proper place, and was so far from losing, that it acquired body. Yet the same red which is so durable in the air, does not resist the trial by tartar. Would it then be proper to proscribe this colour, because that salt discharges it, or are the stuffs we employ for clothing intended to be boiled with tartar, alum, or soap? I do not, however, mean to disapprove of the trial by proofs, they are useful because they are ready, but there are cases in which they ought not to serve as a ground for pronouncing a sentence of confiscation, especially when they cannot show that a colour which should have been dyed for materials for durable colours, has been dyed with those of a fading nature.

179. Upon the whole, then, it appears that the only sure test we can employ, is direct exposure to air and light, for those stuffs which are not to be leyed; and washing with alkalies and soap for such as are to be leyed. And it is the only sure test of the goodness of these substances. In order to try the colours of silk, it is generally thought sufficient to expose them to heat in acetic acid, or lemon juice; and they are considered as good and permanent colours if they stand this test. And, indeed, when the woods...
DYEING.

SECTION III.

Of Stuffs.

CHAP. I. Of the Nature of Stuffs in general.

180. Though a knowledge of the structure of organized bodies, and of the proportions in which their ultimate principles are combined together, can seldom, without the aid of experiment, afford much information respecting their relations with other substances, we cannot doubt that an intimate acquaintance with their mechanical form and composition will throw some light on these relations, and point out the best means of investigating such as cannot be discovered by analogy alone. We shall therefore endeavour to ascertain the mechanical and chemical constitution of the various kinds of stuffs, as a knowledge of these may assist us in discovering the circumstances upon which their attractions for colouring matters depend.

181. The stuffs usually submitted to the operation of dyeing, are wool, silk, cotton, and flax. The two first are of animal origin; the two last are vegetable products. These substances disagree with one another in chemical composition, and are characterised by those differences of constitution which usually distinguish the productions of the animal and vegetable kingdom. Animal substances differ from vegetable products, by containing a considerable quantity of nitrogen, an element which exists but sparingly in vegetables; and also a larger proportion of hydrogen. This difference of chemical constitution is rendered very obvious, when animal and vegetable products are subjected to distillation. The former yield a large quantity of ammonia, the latter seldom give out that substance, but frequently an acid. The former yield much oil, while, in many cases, vegetable products do not yield the smallest quantity. Here, again, animal substances, during their combustion, afford a bright flame, though of short continuance, as it is soon extinguished by the charcoal which is formed; they, at the same time, emit a very pungent odour, owing to the extrication of ammonia, and of the empyreumatic oil, which makes its escape without being consumed. Animal substances are very liable to putrefaction, and during the advancement of the process, evolve much ammonia; while vegetable products suffer more slowly the vinous or acetous fermentation.

182. As substances are most readily decomposed when the elements which enter into their composition are numerous, animal matters are more liable than vegetables to be destroyed by the different agents to which they are exposed. The number of elementary principles which they contain, enlarges in an equal degree the sphere of their chemical affinity; and hence they are also more disposed to combine with colouring matters. Thus the pure alkalies quickly destroy animal substances, because they combine with them, and lose their causticity, while they have little or no effect on vegetables. The nitric and sulphuric acids also act with considerable energy on animal substances; the former decomposes them, extricates the nitrogen, separates the fatty matter, and forms carbonic and oxalic acids; the latter extricates the hydrogen, a small portion of nitrogen, and leaves a carbonaceous residuum.

183. Silk, though an animal product, partakes a good deal of a vegetable nature. It is less disposed to combine with colouring matters than wool, and resists better the action of acids and alkalies. Cotton and flax withstand the action of acids and alkalies more powerfully than wool and silk, the former being destroyed with difficulty even by the nitric acid. These differences are chiefly owing to differences in chemical constitution; but they may be partly ascribed to differences in the conformation of their fibres, and organic structure.

CHAP. II. Of Wool.

184. The different kinds of wool vary chiefly in the general length and delicacy of the fibre. Its qualities depend partly upon the breed of the sheep from which the wool is taken, and partly upon the parts of the animal to which it adhered. The finest wool is brought from Spain; though Berthollet affirms, on the authority of D'Aubenton, that it might be produced in France of a quality equally good, by a little attention on the part of the shepherd. Attempts have been made of late to introduce the Spanish breed of sheep into this country, with the view of rendering us independent of a supply of wool from abroad; but it is probable that change of climate may affect the habits of the animal, and produce alterations on the fleece. It is well known that the nature of the pasture has a considerable effect on the quality of wool. The manufacturer should be able to judge with accuracy respecting the fineness of it; and, as simple inspection is insufficient for the purpose, the fibres should be closely examined with a microscope, and compared with those of other wools, selected as standards.

185. In the raw state, wool is covered by a sort of unctuous matter called yolk, or suint, which preserves it from the attacks of moths, and, on that account, ought not to be prematurely removed. This substance has been examined by Vaquelin, and appears to be a kind of animal soap, having potash for its basis, together with a quantity of fatty matter, and a portion of lime in combination with the carbonic, acetic, and muriatic acids. The wool of healthy sheep is always more abundantly covered with yolk than that of the sickly and diseased.

186. Before wool is submitted to the operation of dyeing, the yolk is removed by scouring or maceration for about a quarter of an hour in water, mixed with a fourth part of salted urine, and heated so as the hand can just bear the temperature. After being duly stirred in this mixture, it is taken out and drained; it is then carried to a stream of running water, and moved about till the greasy matter appears to be completely separated, and ceases to render the water turbid. M. Vaquelin recommends, that the wool, after being cleansed as effectually as possible with pure water, should be soaked for a few hours in a tepid solution of soap, one pound of soap being employed for every twenty pounds of wool to be scoured. M. Roard is of opinion that one pound of Flanders soap, employed in this manner, is sufficient for thirty pounds of wool; he recommends, however, that the water should be heated to 60° of Reaumur, (147° of Fahrenheit.) He affirms
DYING.

187. The wool is dyed in the fleece, or before being spun, chiefly when it is to be manufactured into cloths of mixed colours, and it is dyed after being spun when it is to be made into worsteds. But it is generally dyed after it has been manufactured into cloth.

When wool is dyed in the fleece, its filaments being separate, are in a situation for absorbing a greater proportion of colouring matters than when it is spun, and still more when it is in the form of cloth; but different woollen stuffs vary considerably in this respect, according to their fineness and closeness of texture. These circumstances taken in consideration with the different qualities of dyeing ingredients, prevent us from relying with implicit confidence on the processes usually recommended.

188. After wool has been spun and wove, it is subjected to the operations of felting and fulling. According to the observations of M. Monge, the fibres of wool consist either of a great number of small laminae overlapping one another from the root to the extremity, or of a series of annular concretions, like the horns of animals, gradually decreasing in diameter towards the point. From this structure of the woolly fibre, a hair held by one hand by the root, and drawn between the thumb and finger of the other hand, scarcely any friction or resistance is perceived; but if it be drawn in like manner, in a contrary direction, a tremulous motion is distinctly felt, accompanied with a sensible grating noise. By this conformation of the fibre, a hair when it is pressed must suffer greater resistance, when it slides in the direction of the point, than in that of the root; and to obviate the inconvenience which this would occasion in spinning, wool is covered with some unctuous matter, which in some measure smooths its asperities, and thus facilitates that operation. After the wool is manufactured, the oil being no longer useful, is removed both for the sake of cleanliness, and to enable the stuff to absorb more effectually the dye. The cloth is therefore taken to the fulling mill, where it is beaten with large beaters, in a trough of water, containing diffused through it a quantity of fullers earth. The earthy matter uniting with the oil, forms a kind of soap, which is carried off by the constant action of the machinery, and the effusion of fresh portions of water.

See Wool.

CHAP. III. Of Silk.

189. Silk is of animal origin, and consists of the fine threads with which the bombyx mori, a moth belonging to Linnaeus's third order of insects, envelopes itself before it emerges in the perfect state. Silk is naturally covered with a gummy or glutinous substance, to which it owes its stiffness and elasticity; it is also frequently tinged with a yellowish colouring matter. The purposes for which silk is usually employed, require that it should be freed from both these matters; and this is commonly done by means of soap. Besides the gummy and colouring matters, there is also, according to Board, a substance to be removed, which has a considerable resemblance to wax. He states, that the gummy matter, which is soluble in water, usually amounts to about 24 per cent, and the colouring matter to about 1-57th, or 1-60th part of the silk; the wax seldom exceeds the 1-100th part of the silk, and is frequently less than half that quantity. All these substances are removed by scouring with soap; but this operation must be slightly modified, according to the purposes for which the silk is intended: it ought not to be so complete for silks which are to be dyed, as for those which are to be white, and a difference ought to be observed in the former experiments according to the colour to be given. For common colours, it is generally thought sufficient to boil the silk for three or four hours, in a solution of twenty pounds of soap for each hundred of silk, taking care to fill up the kettle from time to time, to replace the water carried off by evaporation. The quantity of soap is increased for those silks which are to be dyed blue; and still more for those which are to be scarlet, cherry-colour, &c. these colours requiring a brighter ground for their display than such as are of a more delicate hue.

190. Silk which is to remain white commonly undergoes three operations. In the first of these, which is intended to remove the gummy matter, it is kept in a solution of thirty pounds of soap to a hundred of silk, the solution being very hot, but not boiling. When it has been immersed a sufficient length of time for the removal of the gum, which is known by the whiteness it acquires, it is taken out and wrung. In the second operation, the silk is put into bags of cloth, and boiled in a weaker solution of soap for about an hour and a half, taking care to keep the bags constantly stirred to prevent those which touch the bottom receiving too much heat. The third operation is intended to soften the white, and render it more pleasing, by giving it a slight shade of some delicate colour. For this purpose, a solution of silk is employed, the proper strength of which is determined by its mode of frothing; this is slightly tinged with a colour of the shade to be given, and the silk is then moved about in it until it acquires the desired hue. At Lyons, where silk is scourcd of a beautiful white, no soap is used in the third operation; but after the second, the silks are washed, fumigated with sulphur, and azured with river water.

191. Board thinks, that instead of employing the Board's soap at different times, it is more advantageous to employ the whole quantity to be used at once, and by that means shorten the boiling to an hour, or a little more; the silk is thus left with more of its natural softness and lustre, as well as stronger and more elastic. He recommends, indeed, that when it is to be dyed of a crimson, or any other colour which would not be affected by the yellowish tinge of the silk in its raw state, the latter ought not to be completely removed; because, when this is done, the dyed colour possesses less brilliancy than it would otherwise have.

192. As soap seems to impair the lustre of silk, the Academy of Sciences, in 1761, proposed, as the subject of a prize dissertation, to find a method of scouring it without soap; and the prize was adjudged to M. Rigaud of St Quentin, who proposed substituting for soap a solution of soda, or carbonate of soda, so much diluted as not to affect the texture of the silk. But some inconvenience must have attended the practice of this method, as it is not adopted, though generally known, and easy of execution. Board, indeed, affirms, that the gummy matter of the silk is less effectually removed by soda than by soap.

193. The Abbé Collomb has given an account of a Collomb's method of scouring silk by the action of water alone, which deserves attention. Having boiled silk for about
Of Stuff. If three hours in common water, he found that its weight was diminished about one-eighth; and upon repeating the operation, the loss of weight amounted nearly to one-fourth. The silk still retained a yellowish or chamois colour; and though it did not possess a sufficiently bright ground for the more brilliant colours, it answered very well for those which were not affected by the tinge it retained. It took a finer and more glossy black, for example, than if it had been scoured in the usual way with soap.

194. When silk is intended for the manufacture of dyes and gauzes, its natural elasticity and stiffness should be preserved as much as possible; but as the methods usually employed for removing the colouring matter, also deprived of the gum, it became a desideratum to whiten silk without affecting its elasticity. M. Beaume discovered a method of doing this by means of muriatic acid and alcohol. The process, however, is said to be liable to accidents; and, notwithstanding the advantages which it appears to present, it is scarcely employed.

195. Before silk can be dyed, it must be prepared with alum, as without this operation the greatest part of the colours applied would possess neither beauty nor fixity. This preparation consists in mixing, in a tan or vat, about forty or fifty pails of water, with an equal number of pounds of Roman alum, which has been previously dissolved in warm water; the solution being well stirred during the mixture, to prevent the alum returning to the crystallized state. The silk, after being well washed and wrung, to free it completely from any soap which may have adhered to it, is immersed in the alum liquor, where it is allowed to remain for eight or nine hours, after which it is wrung out, and washed in a stream of pure water. The above quantity of liquor is sufficient for 150 lbs. of silk, and with the addition of a little more alum when the solution begins to grow weak, may be used for a fresh portion, as before: this addition may be repeated until the liquor acquires a disagreeable smell, and it may then be employed in the preparation of stuffs intended for dark colours, till all its strength is exhausted. The preparation must be performed in the cold, because the liquor, when it is employed hot, impairs the lustre of the silk. See Silk.

CHAPTER IV. Of Cotton.

Different kinds of cotton. 196. Cotton is the downy substance contained in the pods of a genus of plants denominated *Gossypium*, of which Linnaeus describes five species, the *herbaceum*, *arboresum*, *hirsutum*, *religiosum*, and *barbadense*. The qualities of the cotton vary in these different species, and depend not less upon the climate than upon the plant itself. Great varieties of the gossypium occur in the American islands; but, according to Mr Bennett, the inhabitants have hitherto neglected to choose the most valuable species, and have thus lost much of the benefit which they might have derived from this valuable article of commerce.

External characters. 197. Cottons differ principally in the length of the filaments, their fineness, strength, and colour. The structure of the fibre has not been well ascertained. Lewenhoeck, who examined it with a microscope, affirms, that it has two sharp sides; a convolution which serves to explain the irritating property of cotton, when it is employed in dressing wounds and ulcers instead of lint. Dr Bancroft seems to ascribe the disposition which cotton has of imbibing colours more readily than linen to this mechanical structure; and yet, with some degree of inconsistency, he has bestowed considerable pains to controvert a similar opinion of M. le Prieur d'Apligny. "This author," says he, "endeavoured to explain the cause why colours are less durable when dyed in silk, cotton, and linen, than in wool, by supposing that the pores of the three first of these substances were smaller than those of wool; and that, therefore, colouring particles could not enter into them so easily and freely as into those of wool. But the very reverse of this supposition seems true, there being little difficulty in making silk, cotton, or linen, imbibe colours, even when topically applied cold, without any artificial dilatation of their pores, which is necessary in the dyeing of wool. The real difficulty, therefore, is not in making them imbibe, but in making them retain the colouring particles when imbied; because being admitted so readily into their undilated pores, they cannot be afterwards compressed and held therein by any contraction of these pores, as is done in those of wool. We know that it requires twice as much cochineal to produce a crimson on silk as on wool, which is a proof that it can take up a greater quantity, and consequently that its pores are at least sufficiently large and accessible; we know also, that unbleached cotton is always preferred for dyeing the Turkey red, it being found to retain the colour most permanently; doubtless, because its pores or interstices are less open before than after the operation of bleaching. This is also the case of raw or unscoured silk, which, as the ingenious Mr Henry of Manchester observes, is more easily and permanently dyed than that which has passed the above described process of whitening and scouring, and, indeed, the openness of the pores of cotton and linen, and their consequent readiness to imbibe both colouring particles, and the earthy or metallic bases employed to fix most of them, are circumstances upon which the art of calico-printing is in a great degree founded."—The sentiments of Dr Bancroft respecting the cause of the union and durability of the colouring matter with the stuff, as they are expressed in the passage we have just quoted, seem to agree completely with the exploded notions of Heliot on the same subject. Both refer the operations of dyeing to the dilatation of the pores of the stuff; to the deposition in them of particles of foreign matter; and to the retention of these particles in their new situation, by the subsequent contraction of the pores. No notice whatever is taken of the influence of chemical affinity, but the whole process is described as depending upon mechanical principles. This is the more surprising, as Dr Bancroft, in other parts of his excellent treatise On the Philosophy of Permanent Colours, has distinctly referred the combination of the colouring matter, with the stuff to which it is applied, to the influence of chemical attraction.

198. In order to dispose cotton to receive the dye, it must undergo the operation of scouring. It is sometimes boiled in sour water, but more frequently in alkaline lea. The boiling is carried on for two hours, after which it is wrung out; it is afterwards well rinsed in a stream of water, and then dried. Cotton stuffs are prepared for calico printing by soaking them in water mixed with at most 1-50th of sulphuric acid, washing them afterwards in a stream of water, and then drying them. Berthollet observed, that the acid used in this operation, combined with a quantity of calcareous earth and iron, which would injure the colours.

199. To prepare cotton for being dyed, it must also be
Exposed to the operations of aluming and galling. In the preparation with alum, about four ounces of it are required to each pound of stuff. Some add a solution of soda, in the proportion of 1-10th of the alum; others, a small quantity of tartar and arsenic. The cotton is thoroughly impregnated with this solution, by working it in small quantities; it is then put altogether into a vessel, and what remains of the liquor is poured over it. In this state, it is left for twenty-four hours, and then carried to a stream of water, where it is allowed to remain an hour and a half; or two hours, to remove the superfluous alum; after which it is washed. In the operation of galling, different quantities of galls are employed, according to the quantity of astringents, and the effect desired. The galls powdered are boiled for about two hours, in a quantity of water proportioned to that of the cotton to be galled. The liquor is then suffered to cool to a temperature which the hand can bear, after which the stuff is divided into a number of equal parts, that it may be wrought pound by pound, and what remains after the operation, is poured upon the whole together, as in the process of aluming, already described. It is then left for twenty-four hours, especially when intended to be madderred for black; but for other colours, twelve or fifteen hours are sufficient. When stuffs are galled, which have already received a colour, the operation must be performed in the cold, that the colour may not be injured. See Cotton.

**Section IV.**

**Of Mordants.**

201. The colouring particles seldom have such a decided affinity for the substances usually submitted to the operations of dying, as to form with them a permanent union; it frequently happens, indeed, that the same solvent which deposits the colouring matter on the stuff, will, with equal facility, re-dissolve and erase it. We have already stated, however, that the colouring matters possess very strong attractions for earths and metallic oxides, particularly for the earth of alumine and the oxides of iron; and as these bodies also unite readily with the fibres of which stuffs are usually fabricated, a triple compound may thus be formed, consisting of the stuff, the colouring matter, and the chemical agent having an attraction for both. The substances which serve as a bond of union between the colouring matter and the stuff, are called mordants, a term applied to them from the mechanical action which they were supposed to exert upon the latter, to prepare it for the reception of the dye. As the theory concerning the action of mordants, which first suggested the term, is now completely exploded, Mr. Henry has proposed to substitute in place of mordant, the word basis.

We shall sometimes employ the one term, and sometimes the other.

202. The word mordant is also applied in a more extensive sense, not only to denote those substances which promote the union of the colouring matter with the cloth, and render that union permanent, but all those agents which affect, in any respect, the colouring matter in its new state of combination. Dr. Bancroft has endeavored to apply the term alterants to this class of bodies, their object being not so much to fix, as to vary and modify the shades of adjective colouring matters.

203. The nature of mordants deserves to be investigated with the utmost attention, for though almost all the substances included under this appellation have been discovered by accident, an accurate analysis of their action must tend greatly to improve the principles of dyeing, and give something like a scientific form to its processes.

204. A mordant is not always a simple agent; new combinations are sometimes formed by the ingredients of which it is composed, so that the substances employed are not the immediate agents, but the compounds to which they give rise. The substances which compose a mordant, are sometimes incapable," says Berthollet, "of decomposing each other solely by their own attractions; but the attraction of the stuff for one of their constituent parts brings about a decomposition and new combinations, and sometimes this effect is not produced or completed without the aid of the attraction of the colouring particles. This appears to be the case in the mixture of alum and tartar, one of the most common mordants employed in the dyeing of wool."

205. "I dissolve," continues he, "equal weights of alum and tartar; the latter salt, by this mixture, acquired a greater degree of solubility than it naturally possesses, but by evaporation and a second crystallization, the alum and the tartar were separated, so that they had not decomposed each other. I boiled for an hour half an ounce of alum with an ounce of wool, a precipitate was formed, which I washed carefully; it consisted chiefly of small filaments of wool incrusted with earth; to this I added sulphuric acid, and evaporated to dryness, dissolved it, and obtained crystals of alum. Some carbonaceous particles separated from it. I evaporated the liquor in which the wool had been boiled, but obtained from it only a few grains of alum; the remainder would not crystallize. I re-dissolved it, and precipitated the alumine by an alkali: the precipitate was a slate colour; it grew black upon a red hot coal, and emitted alkali vapours."

"By this experiment," says he, "we see that the wool had decomposed the alum; that a part of the alumine had combined with its most detached filaments, which were least retained by the force of aggregation; that a part of its animal substance had been dissolved and precipitated by the alkali, from the triple combination which it had formed. I made the same experiment with half an ounce of alum, and two drams of tartar; no precipitation took place. I obtained by evaporation a small portion of the tartar, and some very irregular crystals of alum, the rest would not crystallize; this I diluted with water precipitated by potash, and obtained by evaporation a salt which burned like tartar."

He afterwards infers from the whole, "that the wool had begun a decomposition of the alum, that it had united with a part of the alumine, and that even the part of alum which retained its alumine had dissolved some of the animal matter; that the tartar and alum, which
cannot decompose each other solely by their own attractions, become capable of acting on each other when their attractions are assisted by that of wool; that the tartar appears principally useful for moderating the too powerful action of the alum upon the wool, whereby it is injured, for tartar is not used in the alumining of silk and thread, which have less action on the alum than wool has.*

206. Berthollet has shown the attraction of alum for animal substances by an experiment not less decisive: having mixed a solution of glue with a solution of alum, he precipitated the earthy base by an alkali, when the alumine fell down, and carried along with it a portion of combined glue. The decomposition of alum is not so readily produced by vegetable substances, though it is partially effected by the assistance of the astringent principle. When a stuff is impregnated with the latter, and placed, after it has been allowed to dry, in a solution of alum, a combination is established between the alumine and the tamin.

207. The attraction of alumine for the greater number of colouring substances may also be shewn by direct experiment. If a solution of colouring matter be mixed with a solution of alum generally takes place, consisting of the colouring particles combined with alumine. The precipitate is known in the arts under the name of lac or lake, and is more readily formed when an alkali is added to detach the acid, and leave the alumine at greater liberty to unite with the colouring matter. An excess of alkali ought not to be added, however, because alkalis dissolve the greater number of the lakes. M. Thenard has shewn that alumine may even be intimately mixed with several metallic colouring matters, as prussiate of iron, oxide of cobalt, &c.

208. The metallic oxides have also a strong attraction for colouring matters, and when they are presented to the latter in combination with an acid, they frequently quit the solvent, and are precipitated like the alumine in combination with the colouring matter. This class of bodies has also the property of combining with animal substances, and of thus serving as a bond of union between these and colouring particles. But not only have the oxides a strong attraction for colouring particles, and animal matters, but their solutions in acids have the properties which render them less fit to be employed as mordants; and indeed it is generally in this state that they are used in dyeing.

209. In order that a substance may be fit for being employed as a mordant, it is not always sufficient that it should possess an affinity to the colouring principle and the stuff; it must also be perfectly white, otherwise its colour mixing with that of the colouring principle, would produce an intermediate or mixed colour. In some cases, indeed, this may be an advantage, and a substance may be employed both as a colouring matter, and a mordant. Thus the oxide of iron, which, if it were employed alone, would produce a tannic or buff colour, communicates to cotton a violet with madder red; and in like manner, the oxide of tin not only fixes, but greatly exalts several colouring matters. Mordants ought also to be little liable to change, by the action of air and water, the two agents to which dyed stuffs are most frequently exposed. The metallic oxides, from their disposition to attract additional portions of oxygen from the atmosphere, and on that account to suffer changes themselves, as well as to affect the shades of colouring matters, are less valuable as mordants than they would otherwise be.

210. Neutral salts, particularly nitre and muriate of soda, (common salt,) act as mordants, and modify colours; but the nature of their action has been little attended to, and is imperfectly understood. Berthollet found that the muriate of soda was contained in the precipitates produced from some kinds of colouring matter, and that these precipitates contained a considerable degree of solubility; he conceives that a small part of the salt attaches itself to the colouring principle which renders the latter more perfect, but as the changes to which they give rise may be produced by the addition of a small quantity of lime, it is probable that they suffer a partial decomposition, and that when they are used in dyeing, a little of the calcearose base enters into combination with the colouring particles and the stuff.

211. The two mordants most extensively employed at present, are salts of alumine and tin. The former is prepared, according to Berthollet, by dissolving in eight pounds of hot water, three pounds of alum, and one pound of acetate of lead, (sugar of lead,) to which two ounces of potash, and afterwards two ounces of powdered chalk, are added. The alum is decomposed by the acetate of lead, because the oxide of lead combines with the sulphuric acid of the alum, and forms an insoluble compound, which is therefore precipitated; while the alumine is attracted by the disengaged acetic acid, and forms the acetate of alumine. The chalk and the potash are added to neutralize the excess of the sulphuric acid, and to assist the operation of the acetic acid. The substitution of the acetic acid for the decomposition of the alumine, is attended with several advantages. The acetate of alumine being much more soluble than alum, the same quantity of solvent will hold suspended a greater quantity of the former than the latter, and thus present the mordant in a more concentrated state to the stuff; while, on account of its great solubility, it will not be apt to crystallize when mixed with starch or gum, to prepare it for being applied to the block, in topical dyeing. The alumine is also retained less powerfully

* These experiments of Berthollet, which seemed to establish the fact, that a powerful affinity subsists been alumine and the fibres of wool, have been questioned, or rather their accuracy has been distinctly denied by Thenard and Baird. By a series of experiments, of which they have given a minute statement, in a memoir read at the Physical and Mathematical class of the French National Institute, they ascertained, that alum and tartar do not decompose each other when dissolved in water and boiled with wool; that, in this boiling, the wool combines with the alum without decomposing it in any degree, and also with the tartar; and that equal parts of alum and tartar would dissolve in two fifths less of water than would be required to dissolve them separately. They found that wool, as it is commonly cleansed for being dyed, was not deprived of the carbonate of lime naturally combined with it; and that the wool being boiled the usual time, with one fourth of its weight of alum, and one sixteenth of its weight of tartar, produced a copious white sediment, which, being collected, washed, and examined, was found to consist chiefly of a sulphate of lime, and a saturated sulphate of alumine; that when wool had been properly cleansed, and freed from the carbonate of lime, no sulphate was obtained; and that, when in this state, it was boiled in pure water, with the proportions just mentioned of alum and tartar, the residuum of the bath after evaporation was found to consist of alum, cream of tartar, and a compound difficulty crystallizable, composed of tartaric of potash and animal matter. The wool itself softened, by repeated washings, alum and a small quantity of cream of tartar, besides a very small combination of tartaric acid, alum, and animal matter. The results obtained by these chemists have led them to conclude, that, in the process of alumining animal substances, the alum combines with them entire without suffering decomposition. They have also drawn a similar conclusion with respect to stuffs of vegetable origin, viz. cotton and linen.
DYING.

Dr Bancroft mentions, that an acetate of alumine may be prepared more cheaply, by dissolving white lead, not adulterated by carbonate of lime, in strong vinegar, and then adding to the solution a proper proportion of alum. He found also, that licharge, dissolved in vinegar, instead of white lead, was equally useful for decomposing alum. The pyrroligneous acid, as it was formerly termed, may be substituted very advantageously for vinegar, to dissolve the oxide or carbonate of lead; and the acetate of lead thus formed, united with the empirumatic oil which comes over along with the acid, may be employed instead of the common acetate of lead, for decomposing alum. It has also been recently discovered, that lime, dissolved in the pyrroligneous, or other acetic acid, may be employed with still greater advantage for decomposing alum, and forming the acetate of alumine. See Philosophy of Permanent Colours, vol. i. p. 306.

Dr Bancroft's experiments with different salts of tin, showed the liberty of giving an abstract of the results of his experiments. Cochineal, with a solution of tin by nitric acid, only dyed a beautiful crimson or rose colour; and with a solution of that metal by a mixture of tartar and muriatic acid, a beautiful scarlet. The same colouring matter produced, with tin dissolved by a mixture of muriatic and pyrroligneous acid, a dark crimson. Cochineal, with tin calcined by the long continued action of sulphuric acid, dyed a salmon colour; and with a recent solution of tin, it produced a reddish salmon colour, inclining a little to crimson. Tin dissolved by the pure acid of tartar, dyed with cochineal, on cloth, a very lively and beautiful scarlet, inclining a little to orange. A similar colour was produced by water saturated with cream of tartar, in which granulated tin had been kept six weeks. Tin may be readily dissolved by pure citric acid, and more slowly by lemon juice. The solution, freshly prepared, dyed with cochineal a very beautiful scarlet. If it were not too costly, says Dr Bancroft, this solution would deserve the preference of every other for dyeing that colour. Tin dissolved by the pyrroligneous acid, produced with cochineal a colour between scarlet and a rose colour. Phosphoric acid produced a permanently transparent and colourless solution of tin, which, with cochineal, dyed a bright yellowish scarlet. Tin dissolved by fluoric acid, produced with cochineal a very bright scarlet. Tin dissolved by a direct mixture of pure nitric and muriatic acids, in equal proportions, the former of the specific gravity of 1.17, and the latter of 1.17, produced with cochineal, and the common allowance of tartar, a very bright lively scarlet. A similar solution, with an addition of sulphuric acid equal to one-fourth of the nitric, yielded only a salmon colour; the oxide of tin having been precipitated from the common dyers' spirit by soda, and afterwards dissolved by sulphuric acid, was incapable of dyeing, with cochineal, any colour more elevated than orange.

All these experiments show the advantage of using tin as a mordant, or as a substitute to it. A solution of tin is cheap and easy of preparation, and is capable of being employed at all times, without affecting the dye, or the colouring matter. It may, therefore, be recommended as a substitute to the expensive and troublesome preparation of mordants, and the use of it will be found by practical experiment to answer every purpose.

216. Dr Bancroft ascertained, that a muriate of tin, Muric-sulphate of tin, containing only half the quantity of the metal which plate of tin, the acid is capable of dissolving, operated even more successfully in dyeing scarlet, than an equal quantity containing twice as much tin; and he therefore concludes, that nearly one half the tin, which the scarlet dyers commonly dissolve with aquafortis, and a little sea salt, is wastefully employed; a fact, he adds, which, considering the increased price of tin, may, by proper attention, produce a saving of very considerable importance. He found also, that the same quantity of tin dissolved in muriatic acid, combined with about one-fourth of its weight of oil of vitriol, forming what he calls a murio-sulphate of tin, produced excellent ef-

Of Mordants.

Composi-
tion, spirit, or solution of tin.
factors as a mordant. The proportions which he found to answer the purpose best, were about 14 ounces of tin in a mixture of two pounds of oil of vitriol (of the usual strength), with about three pounds of muriatic acid of the specific gravity of 1.17. The muriatic acid should be first poured upon a large quantity of granulated tin, in a capacious glass receiver, and the oil of vitriol afterwards added slowly; and these acids being mixed, should be left for a quarter of an hour to saturate themselves with tin, which they will do in a moment, according to the temperature of the atmosphere, without any artificial heat. The muriato-sulphate of tin, prepared according to the above directions, is perfectly transparent and colourless, and will probably remain so for many years. It will produce fully twice as much effect as the dyers' spirit, or nitro-muriatic solution of tin, at less than a third of the expense. It has also the property of exalting the colours of all the adhesive dyes, says Dr Bancroft, more than the dyers' spirit, and fully as much as the tartrate of tin, without changing the natural crimson of cochineal towards the yellowish hue; and therefore he concludes, after having made a great number of experiments with it, "I think myself warranted in strongly recommending the muriato-sulphate of tin, for dyeing the compound scarlet colour from the cochineal and crimson, and queerziton yellow."

217. Some chemists pretend that the muriate of tin answers the purposes of a mordant most efficaciously when the metal is most highly oxidized; but the experiments of Dr Bancroft, and the results obtained by the writer of this article, lead to the very opposite conclusion. The experience of practical dyers is also at variance with that opinion; for it is well known, that when new the muriate of tin has been long kept, and thus had time to absorb more oxygen, it acts less powerfully in fixing and exalting colours. Constant observation teaches them, that a less lively and agreeable colour is obtained when the solution is made with rapidity, and the disengagement of much vapour, than when it is conducted slowly; doubtless, because in the former case the metal is more highly oxidized. On this account, fresh solutions made with ordinary caution, are preferable to old ones, however carefully prepared.

218. The tin employed in the preparation of the mordants, which have for their bases the oxides of that metal, should be of the utmost purity; common tin being frequently adulterated with copper and lead, each of which is prejudicial to the colour. Malacca, and good English tin, are reckoned the best; though even the latter generally contains a little copper in combination with it. The presence of iron and copper may easily be detected, by pouring a little prussiate of lime into the solution: the precipitate is blue if iron be present, and of a bronze colour if it contains copper.

219. The muriatic acid should also be the purest state in which it can be procured. When it is contaminated with foreign matter, it is perfectly impure and colourless; but it is frequently of a light yellowish appearance, owing chiefly, it is supposed, to the presence of a small quantity of iron derived from the sea-salt, with which procuring the acid. It may be obtained pure, by subjecting it to a second distillation, from a retort connected with a range of Wolfle's bottles, a little muriate of soda having been put with it into the retort, and a gentle heat applied.

220. Chapital has recommended a method of forming the muriate of tin, by causing the vapour of muriatic acid, as it is disengaged from the muriate of soda, to pass through a succession of large receivers, containing granulated tin, with a little water, to absorb the acid. The heat produced by the absorption of the vapour is sufficient to promote a solution of the metal, without the expense of fuel. If the receivers be constructed and adapted to each other, upon the principles of Wolfle's apparatus, the process may, in this way, be conducted with a considerable saving of expense, as no loss will be sustained by the evaporation of the acid, or of the tin in combination with it, which takes place to a considerable extent, according to the ordinary method of effecting the solution.

221. The salts which have already fallen under consideration, constitute the principal mordants used in dyeing, though several other substances are occasionally employed for the same purpose. M. D'Ambourney, of Rouen, has made much use of a solution of bismuth, which had formerly been proposed by M. Folie, of the same city. One part of bismuth is dissolved in four parts of nitric acid; the solution is afterwards introduced into a bath containing tartar, and into which is poured, at the same time, a solution of sea-salt. Perthollet has shewn, that in whatever way this mordant is prepared, there is always formed a precipitate by the addition of water, which renders the colouring matter of a brown colour. Chapital made use of it in dyeing cotton red, for which its author has proposed it; but it was not productive of a greater effect than water acidulated with nitric acid.

222. The oxide of arsenic is also employed as a mordant in dyeing. Vogler appears to have used with advantage a solution of this oxide with potash, in dyeing thread and cotton of a red colour. After dissolving the solution in two parts of water, he added to it a saturated solution of alum. The mixture is at first turbid and gelatinous; but it recovers its transparency, by gradually adding to it a solution of alum. Thread and cotton immersed for twelve hours in this mordant, on being washed and dried, assume, with madder, a very deep colour. The sulphures of arsenic, known by the names of orpiment, realgar, sandarach, yellow arsenic, red arsenic, i.e., are also used in dyeing, particularly in the preparation of indigo. The sulphuret of antimony may be substituted for that of arsenic; but it does not communicate to the colour the same brightness.

223. The corrosive sublimate is also used in dyeing. Wilson employed it in the composition of the aluminous mordant for printing linen, in the proportion of one-eighth of the sugar of lead. It appears, by the experiments of Vogler, that this salt renders the colour of madder darker and more durable.

224. The oxides of lead have been used as mordants, but they tarash the lustre of colours. Vogler obtained a beautiful black, by galloing thread and cotton impregnated with the salt of lead, putting them afterwards in a solution of sulphate of copper, and boiling them in a logwood bath.

225. Some metallic oxides have so strong an affinity for the substances to which they are applied, that they remain permanently fixed on them, and produce colours which are almost indestructible. In treating of the oxide of iron as a mordant in the composition of the colouring matter, we noticed the readiness with which it enters into combination with stuffs, and the easy method of communicating, by means of it, a buff colour to cotton. We have now to remark, that the same substance may also be used as a mordant, to produce, with different colouring principles, violet, prune, and lilac colours. This oxide...
likewise constitutes the basis of black colours; so that it may justly be regarded as one of the most useful substances employed in dyeing, whether in producing colours by itself, or in acting as a mordant to madder red, with tannin, or the astringent principle.

226. The mordant of iron is applied under different forms. Some manufacturers employ the sulphate without any addition; others compose it by dissolving iron in vinegar; some add it to a decoction of rice flour, while others mix it with urine, herring brine, &c. The longer the composition is kept, the better it becomes. At present, instead of the sulphuric, acetic, or other acids, is substituted, as we formerly observed, the pyrrogilous acid, which differs from the acetic by holding the metallic portion in a more permanent state.

227. Mordants are not procured from the earthy and metallic bodies alone; for, under certain circumstances, vegetable and animal substances serve as mordants for each other. Thus, in the complicated process for dyeing Adrianople red, the stuff is first impregnated with an animal substance; the astringent principle is then applied, and after this preparation, the cotton is presented to the alumino mordant. In this case, therefore, the mordant is a triple compound of oil, the astringent principle, and alumine. The astringent principle merits particular consideration, not merely on account of its extensive use as a mordant, but also as a colouring principle. The class of substances included under the head of astringent principles, is rather vaguely defined. Frequently some slight resemblance in taste only has been attended to, and under the name of astringents, alum, and many vegetables possessing very dissimilar properties, have been confounded together, both in medicine and the arts; and more frequently still, every substance which renders a solution of iron black, has been considered as astringent. It does not appear, however, that either the property of corrugating the animal fibre, or producing a dark precipitate with the salts of iron, is sufficiently distinctive of the substances to which the term astringent is usually applied. Many vegetable products, which are decidedly astringent to the taste, afford no black precipitate with the salts of iron; and on the other hand, several substances which yield a copious black precipitate with the salts of that metal, exhibit no traces of astringency. The substance from which the astringent principle is usually extracted, is an excrecence formed on the branches of the oak, and known by the name of gallnut; (See Chemistry; p. 61.) As this is almost the only substance employed to afford the astringent principle for the purposes of dyeing, we shall confine our observations respecting astringents chiefly to its properties.

228. There are different kinds of the gall-nut; some inclining to white, yellow, green, brown, or red; others are ash-coloured, or blackish. They also differ greatly in magnitude, and are either round or irregular, heavy or light, smooth or covered with protuberances. Those which are small, knotted, and heavy, are reckoned the best; they are known by the name of Aleppo galls, and come from Aleppo, Tripoli, and Smyrna. Galls are almost entirely soluble in water by long ebullitions; sixteen drachms afforded Neumann fourteen of extract; from the remaining two drachms alcohol extracted only four grains.

229. The decoction of galls precipitates the oxide of iron of a deep black colour, and forms the well-known substance ink. The solutions of mercury, mixed with an infusion of galls, assumes a brick colour, which soon becomes of a reddish grey. Copper is easily precipitated; the precipitate is at first green, but becomes of an ash grey, and acquires a reddish coppery tinge in drying. Zinc yields a dirty green precipitate. Cobalt forms a light blue precipitate, which quickly becomes of an ash grey.

230. If the astringent property was owing to some individual principle, which was always the same in the different vegetables in which it occurs, the precipitates obtained by their means from a solution of iron, would always form the same compound, and exhibit the same general appearances; but this is not the case. The precipitate produced by galls is of a blackish blue; that of logwood has a different shade of blue; that by oak is a fawn-colour; that by quinquina of a blackish green, &c. These precipitates are also formed with different attendant circumstances, and when fixed on stuffs, are differently affected by alum and tartar. So that the substances denominated astringents form, with iron, different kinds of precipitates, and, consequently, do not derive their properties from an individual principle found in different vegetables. This diversity of properties has induced Dr Bancroft to rank the substances denominated astringents as colouring matters.—I have invariably applied the name of colouring matter," says he, "to those parts of vegetable dyeing drugs which are found to produce colour with an earthy or metallic basis; and I have certainly never been able to discover any good reason for doing otherwise, in regard to those vegetable matters which afford ink, or a black dye with iron; matters which, indeed, are extremely various in their other properties, and even in the sorts of black which they produce; though chemists have, as I think improperly, confounded most of them under the general denomination of astringents; a term which may be unobjectionable, as signifying acerbity in vegetables, but not as indicating, or being invariably connected with, any such property of matter as they have been supposed universally to possess, that of producing a black colour with iron."

231. Although chemists have considered the astringent principle as always the same, experience had taught us that all astringent substances were not equally proper for producing a beautiful and durable black. Of twenty-one species of astringents compared with galls, oak saw dust, and yellow myrobolans, were the only substances which produced a fine black, but inferior in beauty and durability to that obtained by means of the common gall. M. Beunie, who made the comparative trial of their properties in this respect, found that the oak saw dust was preferable to the bark, which is employed by the dyers of thread, and he remarks it is cheaper.

232. Lavosier, Vandermonde, Fourcroy, and Berthollet, were desired to try experiments on the different astringents, for the purpose of making a report on the subject to the academy. The substances upon which they instituted the experiments of comparison, were galls, oak-bark, raspings of heart of oak, of the external part of oak, of logwood, and sumach. To determine the proportion of astringent principal of each of these operations until the substances appeared exhausted; they then mixed together the decoctions belonging to each. They employed a transparent solution of sulphate of iron, in which the proportions of water and
DYEING.

Of Mordants.

Sulphate were exactly known. They first estimated the quantity of the astringent principle by the quantity of sulphate which each liquor could decompose, and afterwards by the weight of the black precipitate which was formed. To saturate the decoction of two ounces of galls, three drams and sixty one grains of sulphate of iron were required, and the precipitate, when collected and dried, weighed seven drams twenty four grains. The decoction of oak bark is of a deep yellow; a very small portion of sulphate of iron gives it a dirty reddish colour, and a larger one changes it into a deep brown. The quantity of sulphate required to saturate the decoction of two ounces of this bark was eighteen grains, and the precipitate, when collected and dried, weighed twenty-two grains. The inner bark of the oak afforded very nearly the same result. The decoction of the rasplings of the heart of oak required for its saturation one drachm twenty four grains, and the precipitate obtained was of the same weight. The decoction of the external wood of the oak produced very little precipitate. The decoction of sumach acquired a reddish violet colour when a small quantity of the sulphate of iron was added. The quantity required for its saturation was two drachms, eighteen grains. The decoction of logwood became of a sapphire blue colour by the addition of sulphate of iron; beyond the point of saturation the blue becomes greenish and dirty. The exact quantity required for saturation was one drachm, forty eight grains, and the weight of the precipitate was two drachms, twelve grains. All the precipitations in which the oak was used took place readily; that by logwood a little more difficulty, but still more easily than that of galls. These eminent chemists afterwards ascertained, that the quantity of astringent substances required to give a black colour of equal intensity, to an equal weight of the same cloth, was proportional to the quantities of astringent principle which had been estimated in each kind by the foregoing experiments; but the black obtained by means of the different parts of the oak, did not resist proofs or tests so well as that produced by galls. It appeared also, that logwood alone was incapable of producing so intense a black as galls or oak, nor was the colour so permanent.

Having thus examined the properties of the astringent principle, with respect to its affinities with solutions of iron, it ought also to be considered with respect to its affinities with stuffs, since its action as a mordant must depend upon its attraction to the latter as well as to colouring matters. Silk acquires by galling, which consists in macerating a stuff in a decoction of galls, an addition to its weight which cannot be taken from it again, beyond a certain, by repeated washings; after which operation, the stuff, when put into a solution of iron, is dyed black, because the astringent principle, decomposing the sulphate of iron, forms a triple compound with the oxide of iron and the stuff.

A galled stuff is also capable of combining with other colouring particles, the colours of which thereby acquire fixity, if they do not naturally possess it, so that the astringent communicates its durability to the triple compound, or perhaps the more complex one which is formed, but the colour is commonly rendered deeper by this union.

As the mordants and colouring particles have a mutual action upon each other, the nature of the latter is often so much altered by their union, that by varying the mordants, we may multiply prodigiously the shades of colour obtained from the same colouring matter. This may be done by simply varying the mode of their application; thus we shall obtain different effects by impregnating the stuff with the mordant, or by mixing the mordant with the bath, by applying heat, or using repeated exsiccations. The greater or less disposition of the stuff to unite with the colouring matter, gives rise to considerable differences in the mode of applying the mordant. If the attraction of the colouring matter to the stuff be strong, the mordant may be mixed with the colouring matter, and in this state both may be presented at once to the stuff; but if it be weak, the compound formed by the mordant and colouring matter might, in this way, be precipitated in the bath without attaching itself to the stuff; and to prevent this inconvenience, the stuff must first be impregnated with the mordant, and afterwards exposed to the colouring matter. In the dyeing of some colours, it is necessary to employ one mordant for the stuff, and another for the colouring principle.

SECTION V.

Of the Processes of Dyeing.

CHAP. I.

General View of the Practical Operations of Dyeing.

In order that a dyeing manufactory may be conducted in the most advantageous manner, Berthollet remarks, it ought to be upon an extensive scale; the subdivision of labour affording an opportunity for each workman, by his attention being directed exclusively to one object, of acquiring dexterity and perfection of execution, while the whole operations are managed in a connected manner, and carried on in detail without loss of time. To these considerations it may be added, that a variety of materials, which, in a small establishment, would be rejected as useless, may often be applied with the utmost success to a different operation. Thus a bath which has been too much weakened for a particular colour, or even for the lighter shades of that colour, may frequently be found serviceable, by affording a ground for other stuffs, or forming a new bath by the addition of fresh ingredients.

A dye-house should be spacious, well lighted, and placed in a situation to command an easy and abundant supply of a stream of good water. The floor ought to be well paved, and proper gutters formed for carrying off dirty water and spent baths. In short, every thing should be constructed with a due regard to cleanliness, both on account of the health of the workmen, and the better performance of the different manipulations.

Dyeing houses should be built in exposed situations, and constructed in such a manner as to exclude the rays of light, while they admit a free current of air.

The caldrons, the size and position of which are to be regulated by the operations for which they are designed, should be made of brass or copper, unless for dyeing scarlet, in the preparation of which it is better to use tin vessels, as well as for other delicate colours in which a solution of tin is employed. Brass is preferable to copper, as it is less liable to be acted upon by saline substances, and thus to spot the stuffs. Vessels of a very large size should be furnished with stop-cocks at the bottom to empty them when necessary; and some contrivance should be employed above.
245. The water employed in preparing the baths should be as pure as possible. In every process, the exact temperature suited to each operation should be carefully attended to; and, in order that the stuff may be fully and equally saturated with the dye in every part, it is necessary to employ precautions, of which few dyers are sufficiently aware, who have not acquired considerable experience in the exercise of their art.

Having made these preliminary remarks, we shall now proceed to give a detailed view of the various processes which are employed for dyeing particular colours, observing the arrangement we proposed to adopt under the head of colouring matters.

CHAP. II.

Processes for Dyeing Red.

246. The colouring matters principally used in dyeing red, and its various shades, are cochineal, kermes, madder, carthamus, arsell, safflower, chay-root, Brazil-wood, sappanwood, camwood, barwood, red saunders, logwood, &c. Each of which we have already described. The shades of red given by these substances are various, and depend partly upon the nature of the colouring matter, and partly upon that of the mordant, with which it is employed.

I. Processes for Dyeing Woollen Red.

247. Of all the red colours communicated to wool by the process of dyeing, the finest and most splendid is scarlet. This beautiful colour is of different shades; sometimes it is required to be of a deeper and more perfect red, at other times to incline more or less to the colour of fire. It is difficult to obtain a particular shade, from the precise proportion of ingredients prescribed; because the quantity of colouring matter contained in different kinds of cochineal varies, and still more, because the solutions of tin differ so much from one another.

248. Dyeing scarlet is usually performed at two operations: the first is called the boiling; the second, the finish or reddening. For the boiling intended for dyeing 100 lbs. of cloth, 6 lbs. of pure tartar are thrown into the water when a little more than warm. The bath is briskly stirred, and when it has become a little warmer, half a pound of powdered cochineal is added, and well mixed. A moment after, 5 lbs. of very clear solution of tin are poured in and carefully mixed. As soon as the bath begins to boil, the cloth is put in and moved briskly for two or three turns, after which it is moved more slowly. The boiling having continued for two hours, it is taken out, aired, and carried to the river to be well washed.

249. To prepare the second bath, which is the reddening, the boiler is to be emptied. When the bath is ready to boil, 3 lbs. of cochineal, powdered and sifted, are put in. These being carefully mixed, when, after having ceased stirring, a crust, which forms on the surface, opens itself in several places, 13 lbs. or 14 lbs. of solution of tin are poured in. If, after that, the bath rises above the brim of the boiler, it must be cooled by the addition of cold water. When the solution is well mixed, the cloth is to be put into the bath, taking care to turn it quickly the first two or three turns. In this bath it is boiled for an hour, pushing it down with a stick when the boiling raises it up. It is then
DYEING.

250. Such is the process for dyeing scarlet, as described by Berthollet. He adds, that the proportions of cochineal and of solution of tin, put either into the boiling or into the reddening, are not fixed. There are dyers who, according to Helot's account, succeed very well by putting two-thirds of the composition, and a fourth of the cochineal, into the boiling, and the remaining third of the composition, with the remaining three-fourths of the cochineal, into the reddening. Helot asserts also, that it does no harm to use tartar in the reddening, provided that not more of it than half the weight of the cochineal be put in; and it has appeared to him even to render the colour more permanent.

This is at present the practice of several dyers.

251. Some dyers do not take the cloth out of the boiling, only refreshing it to make the reddening in the same bath, by pouring in an infusion of cochineal, which they have made apart, and with which they have mixed the proper quantity of composition, i.e. solution of tin. In this way they save time and fuel, and obtain a scarlet equally fine.

Boilers.

252. In dyeing scarlet, it is of advantage to use tin boilers, because the acid employed attacks copper, and the solution it forms with it may affect the beauty of the colour. But as these are difficult to make of any considerable size, and are liable to melt if the workmen forget to withdraw the fire before emptying them, many dyers use copper boilers. It is necessary, however, to keep these very clean, not to allow the acid liquor to remain in them, and to prevent the cloth dyed in them from touching the copper, by means either of a net or a wicker basket.

253. Scheffer directs for the boiling an ounce and a half of solution of tin, with an equal quantity of starch, and as much tartar to every pound of cloth. He observes, that the starch serves to render the colour more uniform; and he directs, to throw into the water when it boils, a drachm of cochineal, to stir it well, to boil the wool an hour, and afterwards to wash it. The wool is then to be boiled half an hour in the reddening bath, with half an ounce of starch, three quarters of an ounce of solution of tin, half an ounce of tartar, and seven drachms of cochineal. It appears, that Scheffer employs a much smaller quantity of solution of tin than Helot; but Helot's solution, the manner of preparing which we described under Mordants (214.), contains much more tin.

254. Pernier describes three principal processes for dyeing scarlet, according as the colour is to be more or less deep, or more or less inclining to orange. He puts no cochineal into the boiling, which he compose of one ounce six drachms of tartar, and an equal weight of solution of tin, added after the tartar is dissolved, for every pound of cloth. After it has begun to boil, he introduces the cloth, and boils it for two hours. For the reddening of the first process, he uses two drachms of tartar, and an ounce of cochineal, afterwards adding gradually two ounces of solution of tin. For the reddening of the second process, he uses the same quantity of cochineal, and two ounces of solution of tin without any tartar. For the third, he directs two drachms of tartar, an ounce of solution of tin, and two ounces of common salt, with the above quantity of cochineal. The scarlet of the first process is of the deepest shade; that of the second is less full, but more lively; that of the third is still more bright and pale.

255. Dr Bancroft states, that he has often given to cloth a scarlet colour at a single but protracted boiling, by mixing the whole quantity of tartar, and solution of tin, and adding the cochineal, after the cloth has boiled ten or fifteen minutes; for such, says he, is the attraction of wool for the colouring matter, as well as for the oxide of tin, that it will take up both very freely, and retain them permanently, when thus mixed. He acknowledges, however, that in this way, the cloth is liable to imbibe both the mordant and the colour, with some inequalities, owing to differences in the quality of the wool; and that it is safest to employ a previous boiling in the way commonly practised. He also mentions, that he has often dyed very beautiful scarlets, by preparing or boiling the cloth with the whole quantity of solution of tin and tartar at once, (as is commonly done with alum and tartar), and afterwards dyeing it unrisned, with the whole of the cochineal in clean water only. In this way he found the colouring particles so completely taken up by the cloth, that the liquor became as clear as the purest water, and the colour was generally very good.

256. After having directed his attention very particularly, and for a long period of time, to the dyeing of scarlet, Dr Bancroft perceived that scarlet was in reality a compound colour, consisting of about three-fourths of a most lively pure crimson or rose-colour, and about one-fourth of a pure bright yellow; and, consequently, that when the natural crimson of the cochineal is made scarlet by the means always bitherto employed for dyeing that colour, there must be a change produced equivalent to a conversion of one-fourth of the cochineal colouring matter, from its natural crimson to the yellow colour; and as a better yellow might be obtained from other drugs where it naturally exists, and at a much cheaper rate than it costs obtained in this way, he concluded that the ordinary method of producing a scarlet was highly injudicious, because unnecessarily expensive.

"Convinced of this important truth," says he, "and at the same time believing too easily, on the authority of Helot, Macquer, and others, that the natural crimson of cochineal was rendered scarlet only by the nitric acid employed to dissolve the tin used in dyeing that colour, I began a series of experiments for producing it, without any such waste of the cochineal colouring matter. For this purpose, it seemed necessary to discover a mordant or basis, capable of permanently fixing, and strongly reflecting the pure vivid cochineal crimson or rose colour, without making it incite to the yellow. I concluded, and found by experiments, that the necessary purity and vivacity of colour could not be obtained from an aluminous basis, however dissolved, though it doubtless fixes the particles of cochineal more durably than any other mordant; and the like defect was found to accompany the solution of all the other earths, as well as of the metals, tin alone excepted; and with this further disadvantage, that most of them either degraded or altered the natural colour of cochineal very considerably. It followed, therefore, that a basis to suit my purpose must be sought for in the pure white calx or oxide of tin, so dissolved or combined, as to reflect the cochineal crimson unchanged, and with the greatest possible lustre. To produce a scarlet, therefore, it was only necessary to superadd, and intimately combine, with this crimson or rose colour, a suitable portion of a lively golden yellow, capable of being properly fixed and reflected by the same basis. Such a yellow I had previously discovered in the quercitron bark, and also in what is properly called young fustic, (Rhyna cotinus), though its colour was less
Dyeing.

247.

Processes of Dyeing.

bright and less durable than that of the quercitron bark. This last had also the advantage of being not only the brightest, but the cheapest of all yellows; since one pound of the bark in powder, which cost but threc- pence farthing, dyed, with a sufficient quantity of mutriate of tin, between thirty and forty pounds weight of woollen cloth, of a full bright golden yellow; and this being afterwards dyed in the same liquor, with one-fourth less of cochineal than what is usually employed, acquired a scarlet, equal in beauty and durability to any which is usually given by the ordinary means with a full proportion of cochineal; and such were the general results of a great number of experiments."

257. Dr Bancroft was accordingly induced to make trial of this method of dyeing scarlet on a large scale, at the dye-house of Messrs Goodwin, Platt & Co. Bankside, Southwark; but owing to the mutriate of tin being either too much concentrated, or too highly oxygenized, the result was far from being attended with the success expected. In a subsequent trial, in which a nitro-mutriate of tin was used, by mixing the mutriatic acid with about one-third less than its weight of the nitric, the mordant acted very feebly, or rather failed in exalting the yellow colour of the bark, which took but slowly on the stuff, and never rose higher than a straw colour; while a considerable quantity of yellow colouring matter, united to the calx of tin, remained floating in the bath, "not because the calx was too intimately combined with the acid, as in the first experiment, but because for want of a sufficient attraction between them, it had been almost wholly decomposed as soon as they were put into water; and in boiling, it fixed itself with the bark colour upon the cloth very sparingly, superficially, and slowly.

258. "As this nitro-mutriate of tin," says Dr Bancroft, "though exempt from the defects of the mutriatic solution, had failed through others of a very opposite nature, I was induced to mix much greater proportions of nitric with mutriatic acid, for dissolving tin, in order to see how much of the former could be used in this way, without so far yellowing the cochineal crimson as to prejudice the use of any of the quicks of the other dyes in the dyeing of scarlet, an effect which I still expected from the nitric acid, when used in a very large proportion; but, to my great surprise, I could discover no such effect, even when I had dissolved the metal in nitric acid alone. At first I suspected some impurity in the acid which had been employed; but having procured a fresh supply, and ascertained its purity by the proper means, I still found that tin dissolved by it, had not the least tendency to change the cochineal crimson towards a yellowish or scarlet hue; and that this effect, in the usual way of dyeing that colour, resulted wholly from the tartar, (acculated tartrate of potash,) which is always employed at the same time. This fact I ascertained by repeated and varied experiments, in which I constantly found that cochineal, with the dyer's common solution of tin, and even with that made by nitric acid only, would produce nothing but a crimson, without tartar; and that cochineal, with tartar, would produce a scarlet, not only with these last mentioned solutions, but also, and equally well, with the mutriatic solution of that metal; and therefore that every thing which had been taught and believed to the contrary, was repugnant to truth. And here I cannot conceal my wonder, that an error of so much consequence, and so destitute of all foundation, should have been propagated and confirmed by so many acute reasoners and sagacious observers in other respects; for, besides other eminent writers, Mr Poerner has more recently adopted and propagated the same error, after making a great number of experiments, several of which, if they had been duly considered, would have taught him the truth on this subject. This was even more lately done by Berthollet, in his Elements de l'Art de la Tinture, where, to adopt the words of Dr. Hamilton's translation, he says, "Tartar, as we have seen, gives a deeper and more rosy hue to the colouring matter of cochineal, precipitated by the solution of tin. It moderates the action of the nitro-mutriatic acid, which tends to give scarlet an orange cast, though this orange cast is not to be seen in the precipitate produced by the solution of tin, which is, on the contrary, of a fine red. That is probable, and it is certain the tin gives scarlet an orange tint by means of the action of the nitro-mutriatic acid exerts on the wool, which, as well as all other animal substances, it has the property of turning yellow. Thus, (adds he,) by putting more of tartar into the reddening, a deeper and fuller scarlet may be obtained; and on the contrary, the scarlet may be rendered more inclining to orange, by omitting this ingredient." Here then it is manifest, (says Dr Bancroft,) that the nitro-mutriates of tin are each supposed to produce effects directly contrary to what are really produced by them, the effects of each being ascribed to the other; a mistake capable of producing much disappointment and detriment. In the last edition of his Elements on Dyeing, Berthollet has accordingly, with much candour, acknowledged his error, and admitted the truth of Dr Bancroft's observations.

259. Had Dr Bancroft's attempts to simplify and improve the method of dyeing scarlet with cochineal, produced no other effect than the correction of a mistake, which had prevailed so long and so universally, the result, even in this point of view, might have justly been deemed important; but the failures which he had hitherto experienced in realizing his speculative opinions, instead of diminishing his confidence in his former reasoning, only increased his diligence in searching after more suitable means for accomplishing his purpose, and length, after various experiments, he discovered that the muri-sulphate of tin, the composition of which we have already described (216.), formed an excellent mordant for the process he had proposed.

260. To dye a scarlet with this mordant, it is necessary to put the cloth, suppose 100 lb. weight, into a proper tin vessel, nearly filled with water, in which about 8 lb. of the muri-sulphuric solution of tin have been previously mixed, to make the liquor boil, turning the cloth as usual through it by the winch, for a quarter of an hour; then taking the cloth out of the liquor, to put it into about four pounds of cochineal, and two pounds and a half of quercitron bark in powder; and having mixed them well, to return the cloth again into the liquor, making it boil, and continuing the operation as usual, until the colour be duly raised, and the bath exhausted, which will be the case in about fifteen or twenty minutes; after which, the cloth may be taken out and rinsed as usual. "In this way," says Dr Bancroft, "the time, labour, and fuel necessary for filling and heating the dyeing vessel a second time, will be saved; the operation finished much more speedily than in the common way; and there will be a saving of all the tartar, as well as of two thirds of the cost of spirit, or nitro-mutriatic solution of tin, which for dyeing 100 lbs. of wool, commonly amounts to 10s.; whereas 8 lbs. of the muri-sulphuric solution will only cost about 3s. There will be, moreover, a saving of at least one-fourth of the cochineal usually employed (which is..."
Dyeing.

Processes of Dyeing.

Dyeing generally computed at the rate of one ounce for every pound of cloth, and the colour produced will certainly not prove inferior, in any respect, to that dyed with much more expense and trouble, in the ordinary way. When a rose colour is wanted, it may be readily and cheaply dyed in this way, only omitting the quercitron bark, instead of the complex method now practised, of first producing a scarlet, and then changing it to a rose, by the volatile alkali contained in stale urine, set free or decomposed by potash or by lime; and even if any one should still unwise to continue the practice of dyeing scarlet without quercitron bark, he need only employ the usual proportions of tartar and cochineal, with a suitable quantity of the muriro-sulphate of tin, which, while it costs so much less, will be more effectual than the dyer's spirit.

261. "Several hundreds of experiments warrant my assertion, that at least a fourth part of the cochineal generally employed in dyeing scarlet, may be saved by obtaining so much yellow as is necessary to compose this colour from the quercitron bark; and indeed nothing can be more self-evident, than that such an effect, *ce tersa paribus* ought necessarily to result from this combination of different colouring matters, suited to produce the compound colour in question."

262. "The scarlet composed of cochineal crimson, and quercitron yellow, is moreover attended with this advantage, that it may be dyed upon wool and woollen yarn, without any danger of its being changed to a rose or crimson, by the process of fulling, as always happens to scarlet dyed by the usual means. This last being, in fact, nothing but a crimson or rose colour, yellowed by some specific or particular action of the acid of tartar, is liable to be made crimson again by the application of many chemical agents (which readily overcome the changeable yellow produced by the tartar), and particularly by calcareous earths, soap, alkali salts, &c. But where the cochineal colouring matter is applied and fixed, merely as a crimson or rose colour, and is rendered scarlet by superadding a very permanent quercitron yellow, capable of resisting the strongest acids and alkalies (which it does when dyed with solutions of tin), no such change can take place, because the cochineal colour having never ceased to be crimson, cannot be rendered more so, and therefore cannot suffer by those impressions or applications which frequently change or spot scarlets dyed according to the present practice."

263. "There is also a singular property attending the compound scarlet dyed with cochineal and quercitron bark, which is, that if it be compared with another piece of scarlet dyed in the usual way, and both appear by day-light exactly of the same shade, the former if they be afterwards compared by candle-light, will appear to be at least several shades higher and fuller than the latter; a circumstance of some importance, when it is considered how much this and other gay colours are generally worn and exhibited by candle light during a considerable part of the year."

264. "To illustrate more clearly," continues Dr Bancroft, "the effects of the muriro-sulphuric solution of tin with cochineal in dyeing, I shall state a very few of my numerous experiments therewith; observing, however, that they were all several times repeated, and always with similar effects:

- 1st, I boiled one hundred parts of woollen cloth in water, with eight parts of the muriro-sulphuric solution of tin, during the space of ten or fifteen minutes; I then added to the same water four parts of cochineal, and two parts and a half of quercitron bark in powder, and boiled the cloth fifteen or twenty minutes longer, at the end of which it had nearly imbibed all the colour of the dyeing liquor, and received a very good, even, and bright scarlet. Similar cloth dyed of that colour at the same time in the usual way, and with a fourth part more of cochineal, was found upon comparison to have somewhat less body than the former; the effect of the quercitron bark in the first case having been more than equal to the additional portion of cochineal employed in the latter, and made yellow by the action of tartar.

"2d, To see whether the tartrite of tin would, besides yellowing the cochineal crimson, contribute to raise and extant its colour more than the muriro-sulphate of that metal, I boiled a hundred parts of cloth with eight parts of the muriro-sulphuric solution, and six parts of tartar, for the space of one hour; I then dyed the cloth unrinased, in clear water, with four parts of cochineal, and two parts and a half of quercitron bark, which produced a bright aurora colour, because a double portion of yellow had been here produced, first by the quercitron bark, and then by the action of tartar upon the cochineal colouring matter. To bring back this aurora to the scarlet colour, by taking away or changing the yellow produced by the tartar, I divided the cloth whilst unrinased into three equal parts, and boiled one of them a few minutes in water, slightly impregnated with potash; another in water with a little ammonia; and the third in water containing a very little powdered chalk, by which all the pieces became scarlet; but the two last appeared brighter than the first, the ammonia and the chalk having each rosetled the cochineal colour rather more advantageously than the potash. The best of these, however, by comparison, did not seem preferable to the compound scarlet dyed without tartar, as in the preceding experiment; consequently, this did not seem to exalt the cochineal colour more than the muriro-sulphate of tin; had it done so, the use of it in this way would have been easy, without relinquishing the advantages of the quercitron yellow.

"3d, I boiled one hundred parts of woollen cloth with eight parts of the muriro-sulphuric solution of tin for about ten minutes, and then added four parts of cochineal in powder, which by ten or fifteen minutes more of boiling, produced a fine crimson. This I divided into two equal parts, one of which I yellowed, or made scarlet, by boiling it for fifteen minutes with a tenth of its weight of tartar, in clear water; and the other, by boiling it with afortieth of its weight of quercitron bark, and the same weight of muriro-sulphuric solution of tin; so that in this last case, there was an addition of yellow colouring matter from the bark, whilst in the former, no such addition took place, the yellow necessary for producing the scarlet having been gained by a change and diminution of the cochineal crimson or rose-colour, and the two pieces being compared with each other, that which had been rendered scarlet by an addition of quercitron yellow was, as might have been expected, several shades fuller than the other.

"4th, I dyed one hundred parts of woollen cloth scarlet, by boiling it first in water, with eight parts of muriro-sulphate of tin, and twelve parts of tartar, for ten minutes, and then adding five parts of cochineal, and continuing the boiling for fifteen minutes. This scarlet cloth I divided equally, and made one part crimson, by boiling it with a little ammonia in clean water; after which I again rendered it scarlet by boiling it in
clean water, with a fourth of its weight of quercitron bark, and the same weight of muri acid sulphate of tin; and this last, being compared with the other half, to which no quercitron yellow had been applied, was found to possess the most colour, as might have been expected. A piece of the cloth which had been dyed scarlet by cochinile and quercitron bark, was, in the first experiment, being at the same time boiled in the same water with ammonia, did not become crimson, like that dyed scarlet without the bark.

"In this way of compounding a scarlet from cochineal and quercitron bark, the dyer will at all times be able, with the utmost certainty, to produce every possible shade between the crimson and yellow colours, by only increasing or diminishing the proportion of bark. It has, indeed, been usual at times, when scarlet approaching nearly to the aurora colour were in fashion, to superadd a fugitive yellow, either from turmeric, or from what is called young fustic (Rhizus colinus); but this was only when the cochineal colour had been previously yellowed as much as possible by the use of tartar, as in the common way of dyeing scarlet; and therefore that practice ought not to be confounded with my improvement, which has for its object to preclude the loss of any part of the cochineal rose or crimson, by its conversion towards a yellow colour, which may be so much more cheaply obtained from the quercitron bark."

"By sufficient trials, I have satisfied myself that the cochineal colours, dyed with the muri sulphur solution of tin, are in every respect at least as durable as any which can be dyed with any other preparation of that metal; and they even seem to withstand the action of boiling soap, such as soberer, and therefore I can not avoid earnestly recommending its use for dyeing rose and other cochineal colours, as well as for compounding a scarlet with the quercitron bark." (Phil. of Perm. Colours. i. 485.) Such are the results of Dr Bancroft’s researches on this very important colour. His experiments certainly deserve the attention of the practical dyer; and, indeed, we understand that a portion of yellow colouring matter obtained from the quercitron bark, or Rhizus colinus, is now very generally employed in this country with cochineal for dyeing scarlet. The tartar is not, however, entirely abandoned, though it is much more sparingly used than formerly.

249. As the reddening which has been used for dyeing scarlet is never entirely exhausted of its colouring matter, but still contains a portion which varies in quantity according to the fineness of the powder to which the cochineal was reduced, and the length of time it has been boiled, it may still be employed to produce shades of a darker cast; but the nature of the residue being somewhat the same, it would be vain to point out the particular colours to be dyed with it, or the ingredients necessary to be added for brighter shades. Every thing, in such cases, must be left to the skill and experience of the practical dyer.

265. As wool is dyed with kermes, by first boiling it half an hour in water with bran; then two hours in a fresh bath, with one-fifth of Rouge alum, and one-tenth of tartar, to which 809. water (42.) is commonly added; after which it is taken out, tied up in a linen bag, and carried to a cool place, where it is left some days. To obtain a full colour, as much kermes as equals three-fourths, or even the whole of the weight of the wool, is put into a warm bath, and the wool is put in at the first boiling. Cloth being more dense than wool, either spun or in the fleece, it requires one-fourth less of the salts in the boiling, and of kermes in the bath. Before the wool which has just been dyed is taken to the river, it may be dipped in a bath of water, a little warm, in which a small quantity of soap has been dissolved. In this way the colour will acquire more brightness, though it will be rendered a little of a rosy or crimson cast.

267. Solution of tin has been tried with kermes as well as with cochineal. Scheffer describes several processes for dyeing in this way, but the colour always inclines to yellow or cinnamon, because the compound formed of its colouring matter and the oxide of tin always retains a yellow hue. Berthollet ascribes this to the action of the acid, but it is more probably owing, as in the case of cochineal scarlet, to that of the tartar. Dr Bancroft affirms, that with the same bases or mordants, the colours from cochineal and from kermes closely resembled each other.

268. The red colour dyed upon wool with madder, is greatly inferior in beauty to that obtained from cochineal or kermes; but it has the advantage of being cheaper and more durable. It is, therefore, often applied to coarser stuffs, which cannot admit of expensive dyes. Before a woollen stuff is put into the madder bath, it is first impregnated with a suitable mordant, by boiling it for two or three hours with alum and tartar. It is then left to drain, and after being slightly wrung and put into a linen bag, it is carried to a cool place, where it is allowed to remain for several days.

269. The quantities of alum and tartar vary in different manufactories. Hellet recommends five ounces of alum and one ounce of tartar to each pound of wool. Poerner diminishes the proportion of tartar, and directs that it should be only one-seventh of the alum; while Scheffer, on the contrary, says, that the quantity of tartar should be double that of the alum. Berthollet found that by employing one half tartar, the colour sensitively bordered more on the cinnamon than when the proportion was only one-fourth. Dr Bancroft states the proportions of the aluminous mordant to be, the alum one-fourth or one-sixth, and the tartar one-twelfth or one-sixteenth of the weight of the stuff."

270. In preparing the madder, the bath must not be allowed to boil, because that degree of heat would dissolve the fawn-coloured particles, which are less soluble than the red, and thus debase the colour. After the water has reached a temperature which the hand can just bear, Hellet directs us to throw in half a pound of the best grape madder for each pound of wool to be dyed, and to stir it well before the wool is put in, which must remain for an hour without boiling; after which it is recommended, in order that the colour may be more effectually fixed, to boil it for four or five minutes at the end of the operation. "Whether the colour be in reality fixed more permanently by boiling the dyed cloths a few minutes, as is commonly practised at the conclusion of the operation, is a question (says Dr Bancroft) which I am afraid to answer, as the results of several trials which I have made were not uniform; but if it should be found expedient to employ a boiling heat for this purpose, all danger of any harm from it might be avoided, by giving it with clean water, in a separate pan, to which the cloths might be removed, after having already imbied sufficient colour, with only a scalding heat; in this way there would be no danger of increasing the extraction of the yellowish-brown colouring matter, or promoting its application either to the cloth, or the aluminous basis." See Phil. of Perm. Col. ii. 227.
271. The quantity of madder employed by Parter is only one-third the weight of the wool, and Scheffer advises only one-fourth. Parter says, that having added to the alum and tartar a quantity of solution of tin of equal weight with the tartar, and after two hours boiling, having let the cloth remain in the bath that had been left to cool for three or four days, he dyed it in the usual way, and obtained a pleasing red. He describes another process, in which, after having prepared the cloth by the common boiling, he dyed it in a bath but slightly heated, with a larger quantity of madder, tartar, and solution of tin; he let the cloth remain twenty-four hours in the bath, and after it had become cold, he put it into another bath made with madder only, and there left it for twenty-four hours. In this way he obtained a pleasing red, a little clearer than the common red, and inclining somewhat to yellow.

272. By composing a bath of cochineal and madder, in the proportion of from two to three, or even four pounds of the latter, with one pound of the former, Dr Bancroft obtained, with the muri-rothiate of tin as a mordant, a scarlet which was little inferior to one procured in the ordinary way, from cochineal alone.

273. Madder reds are sometimes rosed, or heightened in brilliancy, with archil and brazil-wood. This process renders them more beautiful and velvety, but the brightness given them in this way soon fades.

274. Wool may be dyed crimson, of various shades, either by giving it that colour at once, or by first dyeing it scarlet, and then deepening it to the desired shade.

275. To dye crimson by a single process, a solution of two ounces and a half of alum, and an ounce and a half of tartar, to every pound of cloth, is used for the boiling; and the cloth is afterwards dyed with an ounce of cochineal. Solution of tin is commonly added, but in less proportion than for scarlet. The processes employed vary greatly, according as the shade required is deeper or lighter, or more or less distant from scarlet. Some use common salt in the boiling.

276. Archil and potash are frequently used for saddening crimson, and giving them more bloom; but the effect which these substances produce soon vanishes. The boiling for crimson is sometimes prepared from a scarlet bath, by the addition of tartar and alum; and it is even affirmed, that the soupe au vin has more bloom, if both its boiling and reddening be made after scarlet, than when it is dyed in a fresh bath.

277. The colour of scarlet is converted into a crimson, by all those substances which counteract the effects of the tartar and solution of tin, employed for giving the former of these colours. Thus the alkalies, alum, and several other earthy salts, change the colour of scarlet to crimson, which is the natural colour of cochineal. Accordingly, if a stuff previously dyed scarlet be boiled for about an hour in a solution of alum, it will become a crimson, which may be rendered of any required shade, by varying the strength of the solution.

278. Crimmins in half grain are made by substituting madder for half the quantity of the cochineal, and following in other respects the processes for reddening. Other proportions may be employed according to the intended effect.

279. Wool may be dyed red by means of carthamus, but the colour soon changes to orange; and as the red thus imparted is inferior to what is obtained from cochineal, both in point of beauty and durability, the use of this dye for wool is entirely relinquished.
of water. The silk is allowed to remain twenty-four hours in this solution; it is then taken out, and washed in clean water till it ceases to render it turbid. The silk is dyed by boiling it a quarter of an hour with five-sixths of its weight of cochineal, in a small quantity of water.

286. Scheffer describes some variations in his process, by which different shades are obtained. If the silk be wrung out of the solution of tin, left all night in a cold solution of alum, (composed of an ounce to a quart of water,) wrung and dried, then washed, and afterwards boiled with cochineal, it will take only a pale poppy colour. If the silk be steeped twelve hours in the solution of tin diluted with eight parts of water, then left all night in the solution of alum, washed, dried, and passed through two baths of cochineal as before, adding to the second bath a little sulphuric acid, it will assume a fine poppy red.

287. Berthollet remarks, with respect to these processes, that though he varied his experiments in several ways, he was never able to obtain a shade comparable to scarlet; and he adds, that by the information he obtained from persons who assisted at Maquer's trials at the Gobelins, the silk dyed by his process never reached that colour. Scarlet, however, is so much in request, that the attention of several individuals has been excited to discover means of giving it to silk.

Those who have been most successful in France, begin with dyeing the silk crimson; this dye is covered over with one of carthamus, by a process which we shall afterwards describe; and, lastly, they give it a yellow dye without heat. By these means, a fine colour is produced, but the action of the air soon destroys the dye of the carthamus, and darkens the shade.

288. Dr Bancroft recommends the following process:

Soak the silk for the space of two hours, in a solution of the muri-o-sulphate of tin, diluted with about five times its weight of water; take it out of the solution, and let it be moderately squeezed or pressed, and afterwards partially dried; and, lastly, dye it as usual, in a bath prepared with cochineal and quercitron bark, in the proportion of four parts of the former to three of the latter. The colour thus imparted to the silk will approach very nearly to a scarlet. A better body may be communicated to it by a further slight immersion into the diluted muri-o-sulphate of tin, and a second dyeing in the bath with cochineal and quercitron bark. If afterwards a little of the red colouring matter of safflower be superadded, by the usual method of applying it, a good scarlet may be produced.

289. A colour denominated false crimson, to distinguish it from the cochineal crimson, is imparted to silk, by means of Brazil wood. To apply this dye, the silk should be boiled with soap, in the proportion of twenty pounds, of the latter to a hundred of the former, and afterwards alumed. Less aluming is required for this than for grain or cochineal crimson. Having refreshed it at the river, it is dipped in a bath more or less charged with the colour of the Brazil wood, according to the shade to be given. If water containing no earthy salt be employed, the colour will be too red for crimson; but this may be remedied by passing the stuff through a slight alkaline solution, or by the addition of a little alkali to the bath. False crimson may be rendered deeper, by adding juice of logwood to the Brazil bath, after the silk has been impregnated with the latter. To imitate poppy or fire colour, the silk should receive an annotta ground; after which it is washed, alumed, and dyed with the Brazil juice, to which a little soap-suds is usually added.

290. Madder is seldom used for dyeing silk, as its colour is not sufficiently delicate and bright for the purpose. The following processes, however, have been recommended. According to the process of De la Folie, half a pound of alum is to be dissolved in each quart of hot water, to which two ounces of potash are to be added; after the effervescence has ceased, and the liquor has begun to grow clear, the silk must be soaked in it for two hours, and then washed and put into a madder bath. The process of Scheffer is somewhat different: the silk is to be alumed in a solution of four ounces of alum, with six drachms of chalk, for each pound of scoured silk; when a sediment is formed, the solution is to be decanted; and after having become quite cold, the silk is to be put into it, and to be left eighteen hours. It is then taken out and dried, after which it is dyed with an equal weight of madder, when it takes a pretty good, but rather dark colour. Guichlic also describes a process for dyeing silk with madder; for one pound of silk, he orders a bath of four ounces of alum, and one ounce of a solution of tin.

The liquor is to be left to settle, when it is decanted, and the silk carefully soaked in it, and left for twelve hours. It is then immersed in a bath, containing half a pound of madder, softened by boiling, with an infusion of galls in white wine; this bath is kept moderately hot for an hour, after which it is to be made to boil for two minutes. After being taken out of the bath, the silk is to be washed in a stream of water, and dried in the sun. The brightness of the colour may be raised, by afterwards passing it through a bath of Brazil wood, to which an ounce of solution of tin has been added.

291. Carthamus is employed for dyeing silk poppy-colour, a bright orange red, cherry, rose, and flesh-colour. The processes differ according to the intensity of the colour to be given, and the degree in which it is to approach that of fire: but the carthamus bath, which varies in the mode of using it, is prepared in the following manner: After having extracted the yellow matter of the carthamus, and opened the cakes, it is put into a deal trough, where it is sprinkled at different times with soda, well powdered and sifted, in the proportion of six pounds to a hundred. The carthamus being well mixed with the alkali, is put into a small trough, with a grated bottom, lined with a closely woven cloth. When this cloth is nearly half filled, it is placed upon the large one, and cold water is poured on it till the lower trough is full. The carthamus is then set over another trough till the water comes from it almost colourless; a little more alkali is then added, and fresh water poured on. These operations are repeated till the carthamus is exhausted and becomes yellow. The silk being distributed on the rods in hanks, lemon juice, or one of the acids formerly recommended, (82,) is poured into the bath, till it assumes a fine cherry colour. Having stirred the bath well, the silk is dipped in, and turned on the skinn sticks, as long as it appears to gain colour. For poppy colour, it is taken out, wrung, drained, and passed through a new bath, where it is treated as in the former. It is then dried, and passed through fresh baths, washing and drying it after every operation, till it acquires the desired shade. When it has taken the proper colour, it is heightened, by turning it seven or eight times in a bath of hot water, to every bucket of which, about a gallon of lemon juice is to be added.
292. If a poppy or fire colour is to be given, the silk must be first scoured as for white, and then receive a slight annotta ground; but it must not be alumined.

Bright orange red, and deep cherry colours, are treated in the same way as poppy colour, except that they have not the annotta ground. The lighter cherry colours, rose colours of every shade, and flesh colours, are made from baths of the second and third running of the carthamus, which are weaker than the first. The lightest of all these shades, which is a very pale flesh colour, requires a little soap to be put into the bath: this softens the colour, and prevents it from taking too quickly or unevenly.

293. The baths of carthamus are used as soon as they are prepared, and as quickly as possible, as their colour loses much by keeping; and indeed, after some time, entirely disappears. They are also used cold, because the red eculee lose their colour by exposure to heat.

III. Processes for Dyeing Cotton and Linen Red.

Cochineal. 294. Cochineal, which, by the aid of the oxides of tin, imparts the most beautiful of all dyes to wool, communicates to cotton and linen a colour which possesses neither beauty nor durability. If cotton be impregnated, however, with the aluminous mordant, it receives, when dyed with cochineal, a very beautiful crimson, capable of bearing several washings, and of resisting, for some time, the action of the air, though not long enough to deserve the appellation of a fast colour.

Madder. 295. Madder is therefore usually employed for dyeing red, and its various shades, upon cotton and linen; and in this respect it is certainly the most useful of all colouring substances. Its affinity for linen is more feeble than for cotton, but the processes which are employed for fixing it upon the one, are found to answer best when applied to the other; we shall accordingly make no distinction between them.

296. The madder red communicated to cotton, is distinguished into two kinds: the one is called simple madder red, and the other, which is much brighter, and more permanent, Turkey, or Adrianople red. Both are dyed upon the aluminous basis, but with a considerable difference in the subordinate parts of the process.

297. Madder reds also differ greatly, both in beauty and permanency, according to the processes employed. For the common madder red, linen or cotton, after being boiled in a weak lixivium of potash or soda, is to be macerated in a decoction of powdered galls, in the proportion of four ounces to every pound of linen or cotton to be dyed. After it is duly impregnated with the solution of galls, and dried, the stuff is alumined, by soaking it thoroughly in a saturated lukewarm solution of alum, employed also at the rate of four ounces to each pound of linen or cotton, the excess of sulphuric acid having been previously neutralized in the alum, by adding to the solution an ounce of soda for every pound of alum. When this has been done, the stuff is moderately wrung; it is then dried, and afterwards alumined a second time, dissolving for that purpose half as much alum as for the first alumining, and adding to it the residue of the former solution. After this second alumining, it is again well dried, and then rinsed, to remove the superfluous alum which has not united itself to the stuff. The acetate of alumine may be substituted for common alum, with greater advantage to the process, but it would be attended with more expense.

298. The linen or cotton having been thus impregnated with the alumina basis, is to be dyed with the best madder, at the rate of three-fourths of a pound for each pound of stuff. The heat of the bath is gradually raised, so as to make it begin to boil in about fifty minutes, or at most an hour; after the boiling has continued a very few minutes, the stuff is taken out, and slightly rinsed; it is then dyed a second time in the same manner, and with the same quantity of madder. After the second dyeing, followed by the usual rinsing and drying, it is commonly thought expedient to steep the linen or cotton in a lukewarm solution of soap, in the proportion of about two ounces of the latter to each pound of stuff, in order to give greater brilliancy to the red colour, and remove all the uncombined colouring matter. The process is completed by rinsing and drying as usual.

299. The Adrianople or Turkey red possesses a greater degree of brightness than the common madder red, and resists more powerfully the effects of different red agents, such as alkalies, acids, alum, and soap. It appears, from the inquiries of Dr Bancrot, respecting this beautiful dye, that the complicated process by which the Turkey red can alone be dyed, was long ago practised, and perhaps invented, by the inhabitants of Malabar and Coromandel; that a knowledge of it was carried from India to Persia, Armenia, Syria, and Greece, and after a long interval to France, in consequence of the accounts transmitted at different times, by the French ambassadors resident at Constantinople, of the means employed to dye this red, particularly at Adrianople. See Phil. Perm. Col. vol. ii. p. 246.

300. The Abbé Mazes published some experiments concerning this dye, which threw a considerable light on the subject, and the French government, from the information it received, published, in 1765, an instruction under the title of A Memoir containing the process for dyeing spun cotton of the same scarlet red as that of the Adrianople cotton. The directions given in this memoir, were first attempted to be reduced to practice at Rouen, or near that city; but, for a considerable time, with very little success. At present, however, the Turkey red is supposed to be dyed in that part of France as beautifully and durably, as in Greece or any part of the Ottoman empire. The steps of the process are carried on, with considerable modifications, in different manufactories, but as they are generally kept secret, we have little means of selecting those which have been found to answer best. The following description is given by Berthollet of the method followed by M. Clerc, who had the management of a manufactury at Vaudreuil, and sent him patterns of his cotton dyed of a beautiful and durable red.

301. "When a hundred pounds of cotton are to be M. Clerc's dyed, we must begin by scouring it well. This operation consists in boiling the cotton in a ley of soda, marking one degree of the areometer, to which is commonly added the remainder of the bath, which has been employed for passing the cottons through for the white preparation called siccian.

"In order to scour the cotton properly, and prevent it from entangling, a cord is passed through three hawks, each of which weighs a pound, and it is thrown into the ley when it begins to boil; it is carefully immersed, that it may not be scorched by the upper part of the caldron, which should contain about 150 gallons of
Processes of Dyeing.

Second operation. Bath with dung.

Dyeing.

Water for 100 pounds of cotton. The cotton is completely scoured when it sinks of itself in the caldron; it is then taken out, and washed by knot in the river, wrung, and hung out to dry.

"A hundred pounds of Alicante soda (barilla) in coarse powder are put into a tub, with a hole near its bottom to allow the water to run into another tub placed under it; seventy-five gallons of liquor is poured on the soda in the upper tub; when the water which has run into the lower one marks two degrees of the soap-makers' arometer, it is proper for the bath with dung, which is made in the following manner:

"Twenty-five or thirty pounds of sheep dung are mixed with the above ley in a large earthen vessel, and stirred with a wooden pestle, then passed through a hair sieve placed over the vat in which the bath is to be prepared. Twelve pounds and a half of Provence oil are then poured into the vat, and kept constantly stirring with a rake, that it may be perfectly mixed with the ley and the dung; the soda ley is poured upon it, and five buckets of water (each equal to four gallons) are commonly required for a hundred pounds of cotton. The bath being thus prepared, is in a proper state to receive the cotton. For this purpose; some of the bath is taken in a wooden bowl, and poured into an earthen pan set in brickwork, at a proper height for working. A hank of cotton is taken and well wrought with the hands; it is frequently taken up and turned in the pan, and then hung upon a wooden peg fixed to the wall; it is slightly wrung out, and thrown upon a table; and the same operation is repeated with each hank. The table upon which the cotton is thrown ought to be raised eight or ten inches from the ground. A workman takes a hank in each hand, and strikes on the table to stretch the threads; he turns it three times, and then makes a small twist to form a head for the hank, and lays it upon the table. Not more than three hanks should be placed one upon another, as too great weight would squeeze the bath out of the under hanks. The cotton ought to remain ten or twelve hours on the table, and then be hung out to dry.

"Ley of soda also at two degrees of the arometer is taken; and after the vat in which the bath with dung was made has been well cleaned, twelve pounds and a half of olive oil are put into it, and the ley of soda added, while it is kept constantly stirred with a rake, in order to mix the oil completely. This bath ought to resemble thick milk; and that it may be good, it is necessary that the oil should not rise to the surface. Some of this bath is then put into the pan, and the cotton dipped hank by hank, as in the former operation. It is then thrown on the table and beat upon it; it is left there till the next day, and then hung out to dry. For this bath about eight buckets of ley are required.

"Fresh soda is added to the remainder of that first put into the tub, if the water poured upon it has not attained three degrees. For this operation, eight buckets of ley are poured into the vat upon the remains of the white bath, and the cotton is passed through it in the same manner as before.

"The cotton is passed through a ley of soda at four degrees, the working being conducted as already described.

"The cotton is passed through a ley of soda at five degrees.

"The cotton is passed through a ley of soda at six degrees, the same precautions being observed, and then carried out to be dried on very small poles; when dry, it is taken to the river to be washed in the following manner:

"The cotton must be first soaked in the water, then taken out and put upon the horse to drain. Water is repeatedly thrown on it that it may be well soaked, and an hour after it is washed knot by knot, to free it completely from the oil, which is absolutely necessary to its taking the galling well. It is then wrung with the jack and pin, and stretched upon the poles to dry. The cotton, when thus washed, ought to be of a beautiful white.

"For the galling, we must choose good galls in sorts, and having bruised them, put for each hundred pounds of cotton twelve pounds and a half into a copper, and boil them in six buckets of clear river water. Three hours are generally required to boil them sufficiently; and we perceive that this is accomplished when they break readily between the fingers. Three buckets of cold water are then added, and the whole passed through a very close hair sieve, squeezing with the hand what has passed through, in order to separate all the resinous particles. When the water has settled and become clear, the galling is performed in the following manner. Nine or ten quarts of the galling is poured into an earthen pan set in the wall at a height convenient for working; and the cotton is dipped into it by separate hanks, working it well with the hands. It is then wrung with the pin, and carried out to be dried as fast as it is dipped; a precaution essentially necessary to prevent the cotton from growing black. When the cotton is thoroughly dried, we proceed to the aluming, in the following manner:

"The copper in which the decoction of galls was made being well cleaned, eight buckets of river water, and eighteen pounds of Roman alum, are put into it, and the alum dissolved without boiling. When the solution is complete, half a bucket of soda ley at four degrees of the arometer is added, and the cotton then wrought in it hank by hank, as in the galling. It is then spread out to dry, and afterwards washed from the alum, as follows:

"Having left the cotton to soak and drain for an hour upon the horse, each hank is washed separately three times, wrung with a pin, and carried to the tenter ground.

"This operation consists in a repetition of the former ones. A white bath is prepared, similar to that described in the third operation; twelve pounds and a half of Provence oil are put into a vat; and eight buckets of ley, at two degrees of the soapmaker's arometer, added to it; and the bath being well stirred, the cotton is dipped in the manner described in the operation referred to.

"The cotton, after being well dried, is dipped in a ley at three degrees.

"After the cotton has been well dried, it is dipped in a ley at four degrees.

"When the cotton is again dry, it is dipped in a ley at five degrees, and this concludes the dips After being dried, it is washed, galled, and alumed, with the same proportions, and attention to the same circumstances as in the ninth, tenth, and eleventh operations. The cotton has now received all the preparations necessary for taking the dye; and ought to be of the colour of the bark of a tree. A very essential circumstance to be attended to is, never to dip the cotton until it is perfectly dry, otherwise we run the risk of rendering

* Black and white galls in equal quantities.
DYEING.

Processes of Dyeing.

Sixteenth operation.
The dyeing

the colour spotted. When the cotton has hung out upon the poles, it must be frequently shaken and turned, to make it dry uniformly.

"A copper of an oblong square form is generally employed, which ought to be capable of holding about one hundred gallons, in which quantity twenty-five pounds of cotton may be dyed at once. The process for dyeing is begun by filling the copper with water, within four or five inches of the brim, and pouring on a pint-full of bullack's blood, or what is still better, when it can be procured, sheep's blood, (this is equal to about five gallons,) and then adding the lizary (Smyrna Madder). When we wish to obtain a fine bright colour, which penetrates, and has a good body, we commonly mix several kinds of lizary together, as one pound and a half of lizary of Provence, with half a pound of lizary of Cyprus; or if these cannot be had, a pound of that of Provence, with as much of the lizary from Tripoli or Smyrna, allowing always two pounds for one of cotton. When the lizary is in the copper, it is stirred with the rake, to break the eddies or lumps, and when the bath is warm, the cotton is put in on skain sticks, two hanks commonly on each. Care must be taken to immerse it properly, and to turn the cotton on the skain sticks, by means of a pointed stick passed along them within the hanks. This process is continued for an hour; and when the copper begins to boil, the cotton is taken off the skain-sticks, and immersed in it, each hank being suspended, by means of a cord passed through it, to sticks supported over the copper. It is now taken out, and washed knot by knot at the river, wrung with the pin, and dried.

Seventeenth operation. Heightening.

"Soda ley at two degrees is poured into the copper used for scouring, which should hold a hundred and fifty gallons of water, and it is then filled within ten or twelve inches of the brim; four or five pounds of olive oil are then added, and six pounds of white Marseilles soap cut very small; it is kept stirring until the soap is dissolved, and when the copper begins to boil, the cotton is put in, a cord being previously passed through it, to prevent its being entangled. The copper is then covered up, and stopped with rags, loaded and made to boil gently for four or five hours; the cover being now taken off, the cotton should appear finished, and of a beautiful red. The cotton must not be taken out of the copper for ten or twelve hours, because it improves in the bath, and acquires a much greater degree of brightness. It must be well washed, knot by knot, and the operation is complete." See Berthollet, Elem. of Dyeing.

M. Papillon's process, with remarks by Dr Bancroft.

302. The following process, which has a considerable resemblance to the one we have just described, was long practised with great success at Glasgow, by M. Pierre Jacques Papillon, a native of France, and communicated to him by a generous reward to the Commissioners and Trustees for Manufactures in Scotland. By agreement, the process was kept a secret during a term of years, for the benefit of M. Papillon; that term having expired, the process was laid before the public in 1803. In describing the different steps of which it consists, we shall avail ourselves of some very judicious observations of Dr Bancroft, intended principally, he remarks, to explain its difference, where any occurs, with the correspondent operations generally practised at Rouen, as they have been lately published by M. Vitalis.

303. For 100 lbs. of cotton, take 100 lbs. of Alicant barilla, 20 lbs. of pearl ashes, 100 lbs. of quicklime; mix the barilla with soft water in a deep tub, having a small hole near its bottom, which is to be stopped at first with a peg, but covered within by a cloth supported by two bricks, in order that the ashes may be hindered from either running through the hole, or choking it while the ley filters through it. Under this tub another is to be placed to receive the ley; and pure water is to be repeatedly passed through the first tub, to form leys of different strength, which are to be kept separate until their strength has been examined. The strongest required for use must swim or float an egg, and is called the ley of six degrees of the French arco-meter. The weaker are afterwards brought to this strength, by passing them through fresh barilla; but a certain quantity of the weak, which is to mark two degrees of the instrument, must be reserved for dissolving the oil, the gum, and the salt, which are used in subsequent parts of the process. The ley of two degrees is called the weak barilla liquor, the other is called the strong.

Dissolve the pearl ashes in ten pails (containing four gallons each) of soft water, and the line in fourteen pails.

Let all the liquors stand until they become quite clear, and then mix ten pails each.

Boil the cotton in the mixture five hours, then wash it in running water, and then dry it.

Remark by Dr Bancroft: "At Rouen two courses of operations are practised to produce the Turkey red; one is called the grey course, and the other the yellow course. In the former, the cotton, after being alumed, receives no more oil, but goes to the dyeing vessel, retaining the grey colour, which naturally results from its being impregnated with alum and galls in combination. But in the yellow course, the cotton, after being alumed, is again immersed in the oleaginous mixtures or steeps, to be mentioned hereafter, by which it acquires a yellow colour. The grey course may consist either of fifteen steeps, or of nineteen, and the yellow of twenty. The first of these courses has most similarity to that of M. Papillon; and it is this which we shall principally compare with the latter, occasionally noticing any peculiarity in the yellow course.

At Rouen, the first or cleansing operation is performed with a very weak ley of soda containing half a degree of the arco-meter; employing about 150 gallons to 100 lbs. of cotton, which is to be boiled therein six hours, then drained, well rinsed in running water, and afterwards dried. This operation is intended to free the cotton from all impure or extraneous matter; but not to produce effects like those of bleaching, by exposure upon the grass, which, until lately, it was believed would lessen the durability of the colours to be subsequently dyed."

Take a sufficient quantity (ten pails) of the strong barilla water in a tub, and dissolve or dilute in it two balls of oil of vitriol, one pound of gum arabic, and one pound of sal ammoniac, both previously dissolved in a sufficient quantity of weak barilla water; and lastly, twenty-five pounds of olive oil, which has been previously dissolved, or well mixed with two pails of the weak barilla water.

The materials of this steep being mixed, tramp or tread down the cotton therein, until it is well soaked: Let it steep twenty-four hours, then wring it hard, and dry it.

Steep it again twenty-four hours, and again wring and dry it.

Steep it a third time twenty-four hours, after which wring and dry it; and lastly, wash it well, and dry it.
Remark by Dr Bancroft.—"The steep here prescribed, contains three ingredients not employed, so far as I can recollect, by any other person; and one of these, I mean the sulphuric acid, seems to indicate a want of chemical knowledge in M. Papillon; because, by neutralizing the soda, it must obstruct the effect which the latter is intended to produce, (that of rendering the oil miscible with water,) or at least, render a greater proportion of it necessary, in order to obtain that effect. In regard to the other two ingredients, viz. the gum and sal ammoniac, I shall only observe of the former, that the quantity is by much too small to produce any considerable effect, either good or bad, without offering any opinion of the latter, because I am unable to form even a conjecture, respecting the purpose which it may have been intended to answer. Did M. Papillon wish, by these additions, to give to his process some appearance of novelty or peculiarity which might render it more deserving of a reward? At Rouen, the *bain blis* is prepared by steeping twenty-five or thirty pounds of sheep's dung several days in a lea of soda, marking four degrees, which is to be afterwards diluted until it amounts to forty gallons; and the dung being squeezed, and broken by the hands, is afterwards made to pass with the liquor through the bottom of a copper pan, provided with numerous small holes or perforations, into a tub containing twelve pounds and a half of fat oil; and in this the oil and dung are, by sufficient stirring, to be well mixed with the ley, and with each other; and in this mixture, which contains but half the quantity of oil prescribed by M. Papillon, the cotton (100 lbs.) is to be steeped, &c. as directed by the latter. It is highly important after this, and each of the succeeding operations, that the cotton should be thoroughly and completely dried, by a stove heat; that of the open air, in this climate, not being sufficient, even in summer.

This part of the process is precisely the same with the last in every particular, except that the sheep's dung is omitted in the composition of the steep.

Remark by Dr Bancroft.—"At Rouen, this steep is prepared by mixing thirty-eight gallons of ley of soda with ten pounds of olive oil, and stirring them until the mixture becomes uniformly milky; which it will do without much difficulty, and remain so without any separation of the oil, if the quality of the latter be suited to this use; this they add to what may have been left of the former steep, and after mixing them promiscuously, they impregnate the cotton therewith, by the usual treatment; drying it after an interval of twelve hours, first in the open air, and afterwards by a stove heat. This steeping and subsequent drying must be repeated once, twice, or three times, according to circumstances, to be mentioned hereafter.

Between this white steep, and the following gall steep, it is the practice at Rouen to employ three salt steeps, and one cleansing operation. In the first, (called premier sel,) twenty-four gallons of the ley of soda, marking two and a half degrees, are mixed in a tub, with the remnant of the white steep; and with this the cotton is impregnated, and dried as in the former operations. In the next, (called second sel,) the remnant of the last steep is mixed with twenty-four gallons of the ley of soda, marking three degrees, and the cotton steeped therein, and dried as before. In the third, (called troisieme sel,) the remnant of the preceding steep is mixed with twenty-four gallons of the ley of soda, marking three and a half degrees; and with this the cotton is to be impregnated, and dried as before. The residuum of this steep, called silex, is preserved, to be used in the brightening operation.

In the cleansing operation, (called degraisage,) the cotton is steeped one hour in lukewarm water, then wrung by the hands, and afterwards washed in a stream of water, to remove any superfluous or uncombined oil, which, as is supposed, might obstruct the equal application and uniform effect of the following gall steep, and thereby render the colour when dyed unequal. After being so washed, the cotton is to be dried, first in the open air, and afterwards by a stove heat."

Boil twenty-five pounds of galls, bruised, in ten pails of river water, until four or five are boiled away; strain the liquor into a tub, and pour cold water on the galls in the strainer, to wash out of them all their tincture. As soon as the liquor is become milk-warm, dip the cotton into it hank by hank, handling it carefully all the time, and let it steep twenty-four hours; then wring it carefully and equally, and dry it well without washing.

Remark by Dr Bancroft: "This constitutes the eighth operation at Rouen, where, as well as in M. Papillon's process, galls in sorts seem to be now employed, though it was formerly thought by the dyers of Turkey red, (as several of them assured me,) that only the white galls, or those from which, at maturity, the insects had made their escape, were fit for this purpose; the others being supposed to give an injurious brown stain to the cotton. But probably it has been since found, that this stain is removed without any trouble by the subsequent brightening operation. At Rouen, the cotton, as soon as it has sufficiently imbibed the soluble part of the galls, and been very moderately wrung, is spread as expeditiously as possible in the open air, if the weather be dry, or if not, under cover; but the drying is always finished by a stove heat.

Dissolve twenty-five pounds of Roman alum in fourteen pails of warm water, without making it boil; skim the liquor well, and add two pails of strong barilla water, and then let it cool until it be lukewarm. Dip your cotton, and handle it hank by hank, and let it steep twenty-four hours; wring it equally, and dry it well without washing.

Remark by Dr Bancroft: "At Rouen, thirty or thirty-five pounds of the purest alum are commonly employed for this steep, with only seven pails of hot water; adding, when the alum has been dissolved, two gallons only of the lixivium, or ley of soda, marking four degrees. But when these proportions are employed, the cotton is not subjected to a second steep with alum, as directed in M. Papillon's sixth step. Sometimes, however, at Rouen, two steeps, with the aluminous mordants, are employed; and, in that case, twenty pounds of alum are dissolved for the first, and fifteen pounds for the second, leaving an interval of two days between them, during which the cotton should retain its moisture, after being slightly wrung from the first steep. It is, however, to be well dried before it goes into the second.

"This steep is performed in every particular like the last; but when the cotton is dry, steep it six hours in the river, and then wash and dry it again.

"The cotton is dyed in parcels of about ten pounds at once; for which take about two gallons and a half of Dyeing ox blood, and mix it in the copper, with twenty-eight pails of milk-warm water, which are to be well stirred; then add twenty-five pounds of madder, and stir the whole well together. Then having before hand put the ten pounds of cotton on sticks, dip into the liquor,
and move and turn it constantly one hour, during which gradually increase the heat, so that the liquor may begin to boil at the end of the hour. Then sink the cotton, and boil it gently one hour longer. And lastly, wash and dry it. Take out so much of the boiling liquor as will leave the remainder only milk warm, when mixed with as much fresh water as may be required to fill the copper again, and then proceed to make up a dyeing liquor, as before, for the next ten pounds of cotton; and so proceed in succession with the whole.

Remark by Dr Bancroft.—" At Rouen the cotton is dyed in parcels of twenty-five pounds each; and the dyeing vessel is of a quadrangular form, containing about 100 gallons of liquor. One quart of ox blood is employed for each pound of cotton, with two pounds of Provence madder, or one pound of the latter, with one pound of Smyrna madder. Some persons, however, think it best to effect the dyeing by two separate operations, employing half of the before-mentioned proportion of madder for one dyeing, and half for the other; but always taking care not to dry the cotton between the first and second dyeings. There are, moreover, some at Rouen who give cotton another alum steep between these dyeing operations, employing for that purpose half as much alum as was used for the first steep; and afterwards washing, &c. as usual.

Mix equal parts of the grey steep liquor, and of the white steep liquor, taking five or six pails each; tread down the cotton into this mixture, and let it steep six hours, then wring it moderately and equally, and dry it without washing.

Ten pounds of white soap must be dissolved carefully and completely, in sixteen or eighteen pails of warm water; because if any little bits of the soap remain undissolved, they will make spots on the cotton. Add to this four pails of strong barley water, and stir it well. Sink the cotton in this liquor, keeping it down with cross sticks, and cover it up; boil it gently two hours, when, being washed and dried, it will be finished.

Remark by Dr Bancroft.—" This constitutes the fourteenth operation in the first set of grey courses at Rouen; where, after having macerated the cotton with the siuon, they boil it five or six hours with six or eight pounds of white soap, previously dissolved in one hundred and forty-five gallons of water, and in a vessel covered at the top, so as to leave only a very small opening for the necessary escape of the steam, which might otherwise occasion an explosion. The effect of this ebulition with soap, is to dissolve and separate from the cotton all the yellowish brown part of the madder colour which may have been applied to it in the dyeing operation; and by this separation to change the colour from the dull brownish red, which it would otherwise retain, to a bright lively colour, nearly equal to that of the finest cochineal-scarlet. It is only by the singular degree of fixity which the pure red part of the madder acquires, in consequence of the operations just described, that this beautiful red can be obtained; for though the reds given from madder in calico-printing are sufficiently durable for all common uses, they are not fixed sufficiently to bear, without injury, that extent of boiling with soap, which is necessary to separate the yellowish brown part of the colour, and produce the pure vivid red, which results from the operations under consideration. Such, indeed, is the stability of the Turkey red, when well dyed, that some of the persons employed in dyeing it have assured me, that their colours would sustain boiling with soap for the space of thirty-six hours, without injury.

In addition to the steps or operations prescribed by M. Papillon, they employ another at Rouen, called rasage, which is intended to make the red incline more to the rose colour, and at the same time to increase its vivacity. For this operation, for the former quantity of cotton, (100 lbs.), they dissolve in one hundred and forty-five gallons of water, sixteen or eighteen pounds of white soap; and as soon as the liquor begins to boil, they add to it from a pound and a half to two pounds of the crystallized muriate of tin, previously dissolved in two quarts of water, and mixed with eight ounces of single aquafortis; and having equally dispersed this mixture through the boiling solution of soap, by stirring, &c. the cotton is put into it, and boiled with the same pretension as at the brightening operation, until the desired effect has been obtained, which is to be discovered by frequent examinations." See Phil. of Perm. Col. vol. ii. p. 249.

304. Pallis has given a detailed account of the method of dyeing the Turkey red, as it is practised by the Armenians, who had been forced, by the troubles in Persia, to take up their residence in Astracan. The limits which we have prescribed to ourselves, do not permit us to give the process in the author's own words; but the following brief outline will convey some information respecting it. The cotton to be dyed, after being well washed in running water, and dried, is alternately impregnated with fish oil, and exposed to the atmosphere for the space of seven days; the impregnation being performed during the night, and the dyeing during the day. They have ascertained, that other oils do not succeed; and, indeed, they do not use the oil of all fish indiscriminately, but choose that which becomes milky upon being mixed with an alkaline solution. After these repeated impregnations and exsications, they wash the cotton and dry it; they then give it an astrin- gent bath, to which a little alum is added; they dye it in a madder bath, with which calves blood has been mixed; and, finally, they digest it in a solution of soda. It appears, that much of the success of the process depends upon the alkaline bath: The cotton being thrown into it, the bath is made to boil over a steady fire till the colour acquires the proper tint. The workman watches with the utmost care for the moment when it is necessary to take out the stuff, and he will rather burn his hand than miss that opportunity.

305. Notwithstanding the numerous attempts which have been made to improve the Turkey red, and to ascertain the circumstances upon which its beauty and durability depend, the theory of the processes is still involved in much obscurity. The object of impregnating the cotton with oil, is doubtless to afford a ground to the stuff, by which its attraction for the colouring matter is to be increased; and yet the methods usually employed for giving this impregnation, do not seem the most effectual for the purpose. It order that the soda, which is mixed with the oil, may produce suitable effects, it must be used, it is said, in the caustic state, otherwise their combination will be imperfect, and the oil will be applied unequally to the cotton. Now, it is well known, that in this intimate state of union, a caustic alkali and oil form soap; and how the oil thus applied should attach itself to the stuff, we confess we cannot conceive; it is added, indeed, that the oil should be in excess, rather than in a state of absolute saturation with the soda, as it would otherwise abandon the cotton in the subsequent washings or rinsings.
sings without benefiting the dye. It appears to us, that a great part of the oil employed, uniting itself (as it must do) with the caustic soda, can operate merely as a detergent, and that it is only the excess which combines with the stuff, and affords a ground for the colouring matter. In the process followed at Astrakan, the oil is applied immediately to the cotton, without the intervention of an alkali; and at Masulipatam and Pulicat, where the reds are excellent, the cotton is soaked either in the oil of sesameum, or in melted hogs-lard; and being afterwards pressed, to free it from the superfluous oleaginous matter, it is exposed to the sun and air for some days: this operation is repeated three times, after which the cotton is well washed. We may conclude, from these facts, that the union of the soda with the oil is not absolutely essential to the impregnation of the stuff with the latter; and that the object in view may be attained by the direct application of a suitable quantity of oleaginous matter, the cotton having been previously well scoured and prepared for its reception.

506. We are not prepared to speak so decidedly with regard to the effects that may be produced by the dung, or the blood of ruminating animals; though Chaptal, Le Pileur d'Apligny, and Felix, have all given it as their opinion, that whatever effect these substances may have in heightening the vivacity of the colour, they do not at all contribute to its durability. Dr Bancroft has expressed his sentiments on this subject more cautiously and philosophically: After a great number of unsuccessful attempts, which he varied in every possible way, to produce the colour in question from oil, galls, and alum, he has concluded, that the gelatine contained in the dung of ruminating animals, or the albumen which it also affords in a much larger proportion, or some other matter derived from it, and probably from their blood, is essentially necessary to produce that fixity, as well as beauty of colour, for which the Turkey red is so much admired; though at present we only know with certainty of this matter, and this colour, that both may be communicated by the successive applications and operations which have been recently described, but of the particular effect of either we are in a great degree ignorant.” See Philosophy of Permanent Colours, vol. ii. p. 273.

507. The process of galling is attended with several advantages: The acid contained in the decoction of galls decomposes the saponaceous liquor with which the cotton is impregnated, and thus tends to fix the oil in the stuff, while the astringent principle unites with the oil, and forms a compound which is little soluble in water, and has a considerable affinity with the colouring principle of madder. The oil may also owe much of its fixity to its being mixed with the gelatinous matter derived from the dung, and the mixture being afterwards precipitated and attached to the cloth by the tannin of the galls. In confirmation of this opinion, it may be stated, that, by the common process of dyeing madder, red, the addition of a little glue is found to add greatly to the beauty of the colour. In short, were we to advance any theoretical opinion on a subject which is still involved in so much uncertainty, we would venture to offer as a conjecture, that the ultimate effect of the different steps of the process for dyeing Turkey red, previous to the alumming step, is impregnating the fibres of the bottom with a small portion of a leathery oleaginous matter.

508. The other ingredient which enters into the composition of the mordant for this celebrated colour, i.e., alum, which in this case operates in the usual manner, by heightening the madder-red, and giving fixity to the colouring matter. If the impregnation, which we have supposed, actually takes place, it will be easy to explain the increased affinity of the stuff for the aluminous mordant, as well as the superior brilliancy which the latter communicates to the colouring matter. The stuff, partaking of the nature of animal substances, by reason of the operations to which it has been subjected, must possess similar properties with respect to colouring matters, and absorb the dye with corresponding lustre and effect.

309. The mordant composed of these different substances, is undoubtedly the most complicated of any which is employed in dyeing; and it still deserves to be investigated with attention. “It is only from a great degree of precision,” says Chaptal, “in this combination, and a great portion of judgment in the artist who produces it, that a beautiful colour can be expected; but though it be possible for him to conduct himself without error, through the labyrinth of these numerous operations, by taking the clue of experiment as his guide, he will find it very difficult to simplify his progress, or bring it much nearer to perfection. It is only by reasoning on his operations, and calculating the result, as well as the principle of each, that he can hope to become master of his processes, to correct their faults, and to obtain invariable products. Without this, the practice of the most experienced artist will afford nothing in his hands, but the discouraging alternative of success and disappointment.”

CHAP. III.

Processes for Dyeing Yellow.

310. A yellow colouring matter, possessing different degrees of brightness, is afforded by a great variety of substances; but under all its modifications, it has a very slight affinity for stuffs, and must be fixed by the intervention of mordants. The substances from which yellows are usually extracted, are weld, rhiz cotinus or fuscit, sumach, anotta, dyer’s broom, turmeric, and quercitrin: of these, the most important are weld and quercitrin.

1. Processes for Dyeing Wool Yellow.

311. The yellow communicated to wool by weld, has little durability, unless the stuff be previously impregnated with some mordant. Alum and tartar are accordingly employed, and by their means wool acquires from that plant a beautiful and permanent yellow.

312. For the boiling, which is managed in the usual way, Hellot directs four ounces of alum to every pound of wool, and only one ounce of tartar; though many dyers use them in equal quantities. In preparing the weld bath, the plant is inclosed in a bag of thin linen, and prevented from rising in the boiler, by means of a heavy wooden cross. Some boil it till it sinks to the bottom, and keep it there by a cross, while others take it out with a rake, and throw it away.

313. Hellot recommends five or six pounds of weld of every pound of cloth; but the quantity must be proportional to the depth of shade required. Lighter and brighter shades may be obtained by dyeing after deeper ones, water being added at each dipping, and the bath kept boiling; but light shades procured in this
DYEING.

318. When a deeper and more permanent colour is to be given, the stuff should be boiled in the ordinary way, but without either tartar or argol, for the space of an hour, or an hour and a quarter, with about one-sixth or one-eighth of its weight of alum dissolved in a suitable quantity of water; it should then be immersed without being rinsed, with about as many pounds of powdered bark as there were used of alum to prepare the stuff, and turned as usual through the boiling liquor, till it assumes the proper shade. About one pound of clean powdered chalk for every hundred pounds of wool, may then be mixed with the bath, and the boiling continued eight or ten minutes longer, when the yellow will have become both higher and brighter.

319. Woollen stuffs may be dyed of a beautiful orange yellow, by the following process. For every hundred pounds of wool or cloth, take ten pounds of quercitron, and an equal weight of the murio-sulphate of tin; let the bark, in the state of powder, and inclosed in a bag, be first introduced into the dyeing vessel, with hot water; six or eight minutes after, add the murio-sulphate of tin to the bath, and stir the whole well for two or three minutes; after which the cloth is put into the dyeing liquor, and turned briskly for a few minutes. The colouring matter attaches itself so quickly, and at the same time so uniformly to the cloth, that after the commencement of the boiling, the highest yellow may be communicated in less than fifteen minutes, without the smallest danger of its being uneven.

320. When a very bright golden yellow approaching less to the orange is wanted, Dr Bancroft recommends seven or eight pounds of murio-sulphate of tin, with about five pounds of alum, and ten pounds of bark for every hundred pounds of cloth. The bark is first boiled a few minutes, then the murio-sulphate of tin with the alum is added; after which the cloth is dyed, as already directed. By using smaller proportions of the ingredients, pure bright yellows of less body may be obtained, having every variety of shade.

321. Yellows of a delicate greenish tinge may be Greeneish obtained, by employing, in addition to these ingredients, a quantity of tartar. Thus, for a full bright yellow, delicately inclining to the greenish tinge, Dr Bancroft advises eight pounds of bark and six pounds of murio-sulphate of tin, with six pounds of alum, and four of cream of tartar. A little more alum and tartar will render the yellow more delicate, and give it more of the greenish tinge; and when this clean, lively, delicate greenish tinge is desired in the utmost perfection, he recommends these different ingredients to be employed in equal quantity. As these very delicate shades are not required to possess much fulness or body, ten pounds of bark, and the like quantities of murio-sulphate of tin, alum, and tartar, are quite sufficient for dyeing three or four hundred pounds weight of stuffs.

322. In order to dye these very pale greenish shades with exquisite delicacy and beauty, Dr Bancroft recommends to boil the bark with a small proportion of water in a separate tin vessel for the space of six or eight minutes, then to add the murio-sulphate of tin, alum, and tartar, and boil them altogether about fifteen minutes; and afterwards put a little of this yellow liquor into a dyeing vessel, previously supplied with water sufficiently heated. The mixture being properly stirred, the cloth is introduced into it, and dyed as usual; fresh supplies of the yellow liquor being added as it is needed. In this way, the palest and most delicate shades may always be dyed with ease and certainty; and those who have never seen the effects of this process, will hardly, in Dr Bancroft's opinion, conceive the exquisite beauty and delicacy of these pale, but lively, greenish lemon yellows.

323. The colours obtained by these means from Durability quercitron are extremely durable; and are found to resist even the action of strong mineral acids, and of boiling soap-suds, as well as exposure to the air. They last they are enabled to withstand by the good effects of the alum, and more especially of tartar.

324. By employing very small proportions of cochineal with quercitron, and the mordants used in the processes already mentioned, the colour is exalted to a beautiful orange, and even to an aurora. Madder produces the same effect when used with quercitron, but in an inferior degree.
II. Processes for Dyeing Silk Yellow.

325. Before the introduction of quercitron bark, weld was almost the only colouring matter employed for dyeing silk of a plain yellow. The silk to be dyed ought to be previously scoured with soap, in the proportion of twenty pounds of soap to the hundred of stuff, and afterwards alumed, and refreshed or washed after the aluming.

Weld bath.

326. The bath is prepared with two pounds of weld for each pound of silk, and after boiling a quarter of an hour, is passed through a sieve or cloth into a vat. When the temperature is such as the hand can bear, the silk is put in, and turned until the colour is become uniform. In the meantime, the weld is exposed to a second boiling in fresh water; and half the first bath being removed, its place is supplied by a fresh decocction. This bath may be used a little hotter than the first, but care must be taken not to allow it to be so warm as to dissolve any part of the colour already fixed. The silk is turned as before; and in the meantime, a quantity of soda is to be dissolved in a part of the second decoction. After being turned a few minutes, a bank is wrung with the pin, to ascertain if the colour is sufficiently full, and has the proper golden cast; if not, a little more of the alkaline solution is added, until the silk attains the desired shade.

Golden and jonquille yellows.

327. When we wish to produce yellows, with more of a gold or jonquille colour, a quantity of annotta, proportioned to the shade required, is added to the weld bath, along with the silk. If the lighter shades are to be given, such as pale lemon, or canary-bird colour, the silk must be previously well scoured, as the beauty will depend greatly upon the whiteness of the ground to which they are applied. The strength of the bath is regulated by the shade required; and if it be intended that the colour should have a greenish tinge, a little indigo is added to the bath; but this will be unnecessary if the silk has been previously azured. For these lighter shades, a smaller proportion of alum should be used.

328. Scheffer directs, that the silk should be soaked twenty-four hours in a solution of tin, made with four parts of nitric acid, one of common salt, and one of tin, and saturated with tartar; that it should be washed, and then boiled half an hour with an equal quantity of weld flowers. He says, that a fine straw colour is thus obtained, which possesses the advantage of resisting the action of acids. By following this process, says Berthollet, very little tin should be left in the solution, because the acid of tartar precipitates it.

329. "All the different shades of yellow," says Dr Bancroft, "may be obtained with equal facility and beauty, and more cheaply, by employing the bark (quercitron) in its stead, after the rate of from one or two pounds for every twelve pounds of silk, according to the particular shade of colour wanted. For this purpose, the bark, powdered and tied up in a bag, should be put into the dyeing vessel whilst the water is cold; and as soon as it becomes a little more than blood warm, the silk, previously alumed, should also be put in and dyed as usual; and when the higher yellows are wanted, a little chalk or pearl ashes may be added towards the end of the operation, as mentioned for the dyeing of wool.

Lively yellows.

330. "Where shades of yellow, more lively than any which can be given, either by weld or bark, with the aluminous basis only, are wanted, it will be advantageous to employ a little of the muri-sulphate of tin; and but a little of it, because the calx of tin, unless sparingly used, always diminishes the glossiness of silk. To produce the shades in question, it will be sufficient to boil, after the rate of four pounds of bark, with three pounds of alum, and two pounds of muri-sulphate of tin, in a suitable quantity of water, for ten or twelve minutes; and the heat of the liquor being afterwards reduced, so that the hand can bear it, the silk is to be put in and dyed as usual, until it has acquired the proper shade, (which it will do speedily,) taking care, however, to agitate the liquor constantly, that the colouring matter, which would otherwise subside in a considerable degree, may be kept equally dispersed through the liquor." See Phil. of Perm. Col. vol. ii. p. 146.

331. An aurora colour may be communicated to silk by annotta. The silk to be dyed is previously well scoured, with twenty pounds of soap to the hundred of stuff, and then immersed in a bath of water, to which more or less of the alkaline solution of annotta has been added, according to the shade required. The heat of the bath ought to be between that of tepid and boiling water. After the silk has acquired a uniform colour, one of the hanks must be taken out, washed, and wrung, to ascertain the state of the colour; if it is not sufficiently deep, more solution of annotta must be added, and the silk again turned. When the desired shade has been obtained, the silk is well washed, and bated twice by a stream of water, to free it from the superfluous colouring matter, which would only injure the beauty of the colour. The colour thus communicated may be rendered orange, by reddening the silks with vinegar, alum, or lemon juice. The acid saturates the alkali employed in dissolving the colouring matter of annotta, and destroys the yellow shade which the alkali had imparted, while it restores the natural colour of the annotta, which inclines a good deal to red.

332. A yellow of great brightness, but little durability, may be dyed upon silk by turmeric. Two processes are recommended by Guillac, which appear to be in substance the same. The first consists in aluming in the cold for twelve hours, a pound of silk in a solution of two ounces of alum, and dyeing it hot, but without boiling, in a bath composed of two ounces of turmeric, and a quart of aceto-citric acid, mixed with three quarts of water; by the second process, the colouring matter of the turmeric is extracted by aceto-citric acid, and the silk alumed, isdyed, either cold, or only moderately warm.

III. Processes for Dyeing Cotton and Linen Yellow.

333. Cotton is prepared for the yellow dye by previously scouring it with a ley composed of the ashes of the stuffs, green wood; it is then washed, dried, and alumed with one-fourth of its weight of alum; after twenty-four hours it is taken out of the aluming and dried without being washed. A weld bath is then prepared, in the proportion of a pound and a quarter of weld for each pound of cotton, into which the cotton is immersed and wrought in it till it acquires the proper shade. It is then taken out, and soaked for an hour and a half in a solution of sulphate of copper or blue vitriol, in the proportion of one-fourth the weight of the cotton. Lastly, it is thrown, without being washed, into a boiling solution of white soap made with the same proportions; and after being duly stirred and boiled in it for nearly an hour, it is well washed and dried.

334. When a deeper yellow is required, the cotton Deep yellow is not alumed, but two pounds and a half of weld are low.
employed for each pound of cotton, to which a dram of verdigris, mixed with a part of the bath, is added. The cotton is dipped and wrought in this bath until it has acquired an uniform colour; it is then taken out that a little ley of soda may be added; after which it is returned into the bath, and kept there for a full quarter of an hour, when it is taken out, wrung, and dried.

335. Lemon colour is dyed by the same process, with this difference, that only one pound of weld is employed for each pound of cotton, and that the proportion of verdigris is diminished, or even entirely omitted, and alum substituted in its stead. The shades of yellow may thus be varied in many different ways.

336. A more vivid and lasting yellow may be given to cotton by the following cheap process, recommended by Dr Bancroft. Take a sufficient quantity of the acetate of alumine, formed by dissolving after the rate of one pound of sugar of lead and three pounds of alum, and the cotton or linen being properly cleansed, immerse it in this mordant, (which ought to be about blood-warm,) for the space of two hours; let it then be taken out and moderately pressed or squeezed over a proper vessel, to prevent the unnecessary waste of the mordant; this being done, let it be well dried in a stove heat, where it can be conveniently applied, and then soaked again in the aluminous mordant; it is then taken out, and again pressed or squeezed as before, after which, without being rinsed, it is thoroughly wetted in as much, and only as much, lime water as will conveniently suffice for that purpose, and afterwards dried. If a very full, bright, and durable yellow be wanted, it may be proper to soak the stuff a third time in the diluted aluminous mordant, and after drying, wet it a second time with lime-water, and dry it again; but in either case, the cotton or linen, after its last immersion, should be well rinsed in clear water, to separate the uncombined particles of the mordant, which are always injurious in the dyeing bath. The lime water produces a more copious deposition of the alumine upon the stuff, while, at the same time, it leaves a portion of calcareous matter united with the mordant, a circumstance of considerable utility for the subsequent raising of the colour.

337. The bath is prepared by taking the quercitron bark powdered, and inclosed in a linen bag, at the rate of from twelve to eighteen pounds for every hundred pounds weight of cloth, and putting it into the dyeing vessel, containing a suitable quantity of cold water; a small fire is then lighted, and immediately after the cotton or linen is introduced and turned for the space of an hour or longer, during which the water should gradually become warmer, but never warmer than the hand can bear. At the end of the time mentioned, the fire may be gradually increased until the liquor begins to boil, after which the stuff may be allowed to remain in it for a few minutes only, because longer boiling always renders the colour of a brownish cast. The linen or cotton having thus acquired the proper shade of colour, is taken out, rinsed, and dried as usual.

338. "All the different shades of yellow," says Dr Bancroft, "may in this way be dyed from quercitron bark. If it be used sparingly with a very moderate heat, and the operation continued only for about half an hour, a pale, though lively yellow, will result; if used more copiously, and the operation continued somewhat longer, a fuller colour will be produced; and this may be raised higher and higher, according as the heat and proportion of bark are increased, and the dyeing operation prolonged, so as indeed to produce a very dark brownish yellow, if the liquor be made to boil for half an hour." See Phil. of Term. Col. ii. 155.

CHAP. IV.

Processes for Dyeing Blue.

339. The substances which are employed for dyeing blue are few in number. The only vegetable products used for this purpose being indigo and woad; Prussian blue being scarcely ever employed as a dye. Vegetables yield by solution a carbon of a very fine blue; and it seems probable, that when the blue colour is obtained by fermentation, as is the case with indigo, the carbonaceous matter is nearly set free, and remains combined with an oil, which gives additional fixity to the colour, and indicates the most suitable solvent.

1. Processes for Dyeing Wool Blue.

340. Various methods are employed for dyeing blue by means of indigo. To enter into a minute detail of these would be foreign to the object of this Work; and we must, therefore, restrict ourselves to a general view of such processes as appear to be best. The bath for dyeing blue is not prepared, as for other colours, in a copper, but in a wooden vat, which is sunk into the ground so as to be only breast high above it; and as it is of great consequence to preserve the heat of the bath, the vat is placed in a situation where it is least apt to cool.

341. Blue may be dyed with pastel or woad, which Pastel or gives a permanent but not deep blue; but if indigo be mixed with them, vats will be obtained very rich in colour; and indeed these are almost the only ones used for wool or woollen stuffs. They are called pastel or woad vats, to distinguish them from those in which indigo alone is used.

342. The celebrated woody vat, so generally employed for dyeing blue, is more complicated than any we have hitherto mentioned. The operations which are employed in different manufactories vary a good deal from one another; we shall select the description of one, which, in the opinion of Chaptal, is the most perfect of any with which, in the course of his extensive experience, he was acquainted.

343. Four hundred pounds of wood, well divided, Preparatio are put into a vat seven feet in depth by five feet in of a woody var. diameter. Thirty pounds of wood are then put into a caldron, to which, after three hours boiling, are added twenty pounds of madder and an equal quantity of bran. The ebullition is afterwards continued for half an hour, when the bath is recruited with twenty buckets of water. The wood is then withdrawn, and the bath allowed to become clear, after which it is returned into the vat. The bath is then raked or stirred for half an hour, after which the vat is covered, and at the end of six hours again raked during another half hour. This operation is repeated at the end of every three hours. When blue streaks make their appearance on the surface of the liquid, eight or nine pounds of quickline are mixed with it, which the workmen term giving bottom to the vat. They also introduce, at the same time, indigo triturated with water, which is used in the proportion of from 10 lbs. to 30 lbs. according to the shade of colour required. The raking is continued at the intervals prescribed, until the blue froth, already mentioned, be formed on the surface of the liquor, after which it begins to work. The vat is then
DYEING.

When the bath is used either in too great or in too small a proportion, it occasions two very troublesome consequences. In the first case, the colour becomes black, the colour is putrid, and the stuff immersed in the bath comes out of a pale grey colour; in the second, the colour becomes rusty, the matter at the bottom is raised up, the smell is fetid, and, in short, a state of putrefaction has commenced.

The first state of the vat is corrected by adding to the liquor madder, bran, urine, tartar, &c.; by reheating the bath; by leaving it at rest without being raked, and by throwing into it a basketful or two of fresh wood. The putrefactive state is corrected by the addition of lime; by frequent raking, &c.

When cloth is to be dyed in a woad vat, the bath is stirred about two hours before the immersion of the stuff; and to prevent the latter coming in contact with the sediment at the bottom of the vat, it is supported by a netting, stretched upon iron or copper hoops, which are fastened with cords to hooks on the sides of the vat. When wool is to be dyed, another netting is put over it, to keep it under the surface of the bath. By means of this apparatus, the stuff, previously wrung out of tepid water, is introduced into the vat, and kept there a longer or a shorter time, according to the degree of strength wished to be given to it. After being taken out, it is wrung above the dyeing vessel, and exposed to the air, when the green colour which it had imbibed in the bath is instantly changed into a blue, by the absorption of the oxygen of the atmosphere. In a rich bath, it is difficult to give an uniform colour to light blues: The best method of obtaining such shades, therefore, is to use vats already exhausted, and which are beginning to grow cold.

That none of the indigo adhering to it may be lost, the stuff is first rinsed in a tub; it is then put through running water, and dried in the shade. When the colour is dull and muddy, the stuff is passed through boiling water, in order to free it from any extraneous impregnation. Stuffs which are of a very deep blue, ought even to be carefully cleansed by filling them with soap, which will tend to equalize the shade without affecting the colour.

A vat in which indigo alone is employed, without either pastel or woad, is called an indigo vat. The vessel used in preparing it is a copper, which being of a conical shape, leaves between it and the surrounding brick-work a sufficient space for containing the fire. Into this copper is poured about forty buckets of water, (more or less, according to its capacity,) in which have been boiled six pounds of salt, tartar or potash, twelve ounces of madder, and six pounds of bran. The whole of this mixture, ground and all, is put into the vat; six pounds of indigo, ground in water, are then to be put in, and, after raking carefully, the vat is to be covered, a slow fire being kept up round it. Twelve hours after it has been filled, it is to be raked a second time; and so on every twelve hours, till the liquor becomes blue, which happens in about forty-eight hours. If the bath has been well managed, it will then be of a fine green, covered with coppery coloured scales, and a blue scum or flower. The theory of the process for preparing this bath is the same as for the preceding, the principal difference consisting in the indigo being dissolved by means of an alkali instead of lime. The dyeing process is conducted with it in the same manner.

Hellot has described two indigo vats, in which the colouring matter is dissolved by means of urine. A quantity of madder is added to both; and in the one vinegar, in the other alum and tartar, of each a weight equal to that of the indigo. The quality of urine must be considerable. Berthollet thinks it probable, that the indigo, deprived of its oxygen by the urine and madder in a state of fermentation, is dissolved by the amoniac which is formed in the urine, either by the action of the heat, or the putrefactive process. These vats, it must be remarked, are by no means comparable with that of pastel, or that of indigo already described, much less work being expended by them, so that they are adapted only to small dye-houses.

Another preparation for dyeing blue with indigo is obtained by dissolving it in sulphuric acid. The resulting compound, which we shall call the sulphate of indigo, was first applied to the purposes of dyeing at Grosheain in Saxony, and hence the dye which it affords is usually known by the name of "Saxon blue." It is also sometimes called the chemical blue of Perner.

Bergman made many experiments, with the view of ascertaining the best method of dissolving indigo in sulphuric acid, and applying it in that state as a dye. From these he concluded, that if the sulphate of indigo has hitherto afforded a dye of little permanency, it was entirely owing to the acid being used in too diluted a state. He accordingly used the sulphuric acid in a very concentrated state, putting one part of indigo, finely powdered, into eight parts of the acid, of the specific gravity 1.9. The mixture was made in a glass vessel slightly stopped, and was accompanied with a considerable heat. After a digestion of twenty-four hours in a heat of 30 or 40 degrees, (from 80° to 104° of Fahrenheit,) the indigo was dissolved, and formed an opaque black solution. By the gradual addition of water, the intensity of colour was reduced, and exhibited in succession every shade of blue. In several experiments described by that illustrious chemist, he kept the stuff to be dyed twenty-four hours in boiling water, and then put a given weight of it into the bath, more or less strong, till the colour of the bath was exhausted. From these experiments he ascertained, that one part of indigo would, in this way, produce a deep blue on two hundred and sixty parts of stuff, which appeared to be then saturated with the colouring matter.

This blue penetrates into stuffs with difficulty; and in order to obviate this inconvenience, Quatremere and Perner have recommended an addition of potash to the acid. The alkali renders the colour more lively, full, and penetrating. A mixture of two parts of indigo in a solution of one part of potash will dye a cloth perfectly. The mixture is to be stirred for some time. After having stood twenty-four hours, one part of good dry potash in fine powder is added; the whole is again well stirred, and, having stood twenty-four hours longer, more or less water is gradually added. Instead of potash, Dr Bancroft has used clean chalk, and sometimes even in such quantities as to saturate the acid. The indigo was then precipitated with the chalk, and being collected in a solid mass, it was found to be still capable of dyeing a blue on wool, though it
Dyeing.

Acids for was and one and will be but two. The process of dyeing with Saxon blue is also introduced. By one and the other; dry it; work it again; and in short, use every means which his ingenuity can suggest for rendering the colour uniform. The stuff should always be washed and beetled between the dryings, and in every dip introduced into the bath in a wet state. After the proper colour has been obtained, it is dried on the tenters in the open air, either in the sun or the shade.

Prussian blue.

In the history of colouring matters, the allusions to Prussian blue are numerous, and have been made to dye cloths by means of Prussian blue. We shall now describe some of the processes which have been proposed for this purpose. Two methods have been suggested by Macquer, neither of which can be said to be attended with the desired effect. In one he soaked the stuffs in a solution of alum and sulphate of iron, and then in a diluted prussiate of potash, containing an excess of prussic acid; and lastly, in water acidulated with sulphuric acid, to dissolve that portion of the oxide of iron not combined with the prussic acid, which the uncombined alkali had precipitated. By repeating successively these immersions, he at last obtained a fine blue, but very unequal; while the stuffs, by the action of the sulphuric acid and the alkali, had become harsh to the touch. It is easy to see, that this process could not succeed. For, as Berthollet remarks, since an alkali not saturated with prussic acid was used in the second immersion, that part of the alkali which was not saturated must dissolve more or less of the blue taken up in the first. If any one, therefore, should repeat these experiments, he ought to employ an alkali saturated with prussic acid, or perhaps lime water, or rather magnesia, both of which have the property of combining with that acid.

Another process.

In Macquer's second process, the stuffs to be dyed were boiled in a solution of alum and tartar, and afterwards in water containing Prussian blue, diffused through it in a finely powdered state. They were now dyed uniformly, but the colour was faint, and seemed merely to be united mechanically with the fibres of the stuffs.

Process of Macquer.

Roland de la Platriere has published an account of another method of dyeing with Prussian blue, which in many respects has a considerable resemblance to Macquer's second process. On fine Prussian blue, in the proportion of a pound to a piece of stuff, powdered and passed through a very fine sieve, he poured in a vessel of delft ware as much muriatic acid as reduced it to the consistency of a syrup. The mixture, which immediately began to ferment, was well stirred for about half an hour; it was then considerably diluted with water, and stirred every hour for a day, till the fermentation ceased, and the particles of the Prussian blue, in a state of very minute division, were intimately united with the acid. Into a trough, narrower than those usually employed, but widening more towards the top, being two feet and a half high, two feet and a half diameter at top, and two feet at bottom, seven or eight buckets of water were poured for one piece of stuff. The colouring composition, well diluted with water in a separate vessel, was then added, by pouring it into the bath through a very fine sieve. When the stuff was placed on the winch over the trough, the bath was briskly agitated, and at the same time the stuff was let down quickly into the bath, and worked as fast as possible for two or three hours. As the Prussian blue is only in a state of mechanical solution, the particles are very apt to be unequally deposited upon the stuff, and it therefore requires the utmost attention on the part of the workman to prevent this taking place. He must work and rework the stuff; wash those parts which may have taken too deep a shade in the bath itself; work it over again, now one end first, then the other; dry it; work it again; and in short, use every means which his ingenuity can suggest for rendering the colour uniform. The stuff should always be washed and beetled between the dryings, and in every dip introduced into the bath in a wet state. After the proper colour has been obtained, it is dried on the tenters in the open air, either in the sun or the shade.

Dr Bancroft has also proposed a method of dyeing with Prussian blue, which does not seem to labour under the disadvantages hitherto attending its use as a dye. By reflecting that the inequality of colour to which the dyeing with this substance is liable, was probably owing to the difficulty of applying the ferruginous basis equally to all the fibres of the stuff; he boiled up what he conceived to be suitable proportions of sulphate of iron with quercitin bark, fusill, and logwood, separately, (these vegetable dyeing drugs having been chosen, not on account of their colours, but their cheapness,) and applied the oxide of iron in this state of combination to the cloth, which by this means appeared to have imbied it uniformly. He then immersed it in warm diluted prussiate of potash, neutralized by sulphuric acid, when the stuff became beautifully blue; and though he admits there were some inequalities in the colour of one of the pieces, he ascribed it rather to his own want of attention to the proper stirring and management of the dyeing liquor, and of the cloth, than to any unavoidable difficulty in giving evenness to the dye. The Prussian colouring matter must be used in a moderate heat, otherwise it will be precipitated by the sulphuric acid, and rendered unfit for the purpose, unless dissolved again by potash, lime, &c.

The colour produced by these processes is one of the most beautiful obtained in dyeing, and suffers no change by exposure to the air in all its vicissitudes. Roland de la Platriere left patterns of it in the open air for six months together. For a long time the colour gained in vivacity, and at last lost but little. Acids are not injurious to it; and boiling with alum even produces in it but little alteration. Dust, however, and rubbing on the creases of it, soon tarnish it; and it is instantly affected by the slightest touch of an alkali.

II. Processes for Dyeing Silk Blue.

Silk is dried blue, by employing the indigo vat. (348.) already described. Sometimes a larger proportion of indigo is employed than is there directed, but nearly the same quantities of bran and madder. Macquer states, that if half a pound of madder be employed for every pound of salt of tartar or potash, the vat becomes greener, and its colour is more fixed in the silk, without being of a less pleasing cast. The pastel or woad vat is not used for dyeing silk, because it does not readily impart to it a sufficiency of colour. When
the bath has undergone its usual course, it is refreshed with about two pounds of potash, and three or four ounces of madder; it is then raked; and in four hours it is fit for boiling.

360. Before being immersed in the bath, the silk is boiled with soap, in the proportion of thirty pounds of the latter for every hundred pounds of the former; and afterwards well cleansed from it by two or more beatings at the river. As silk is apt to take the dye unequally, it is necessary to dye it in small portions, one hank being dipped at a time, by applying it to a wooden cylinder, and turning it once or oftener in the bath. It is then well wrung and aired, to change the green colour to a blue. When it has assumed the proper shade of colour, it is thrown into clear water, and then wrung repeatedly with the pin. Lastly, it is dried as speedily as possible. In winter, and in damp weather, it should be dried in a chamber heated by a stove, and hung upon a frame kept constantly in motion.

361. When it is required to give silk a deep blue, indigo alone is insufficient for the purpose; it must first receive a ground from some other colouring matter. For the Turkey blue, which is the deepest, the silk must be prepared in a strong bath of archil; and, for the Royal blue, one of the same kind, but weaker. A blue, equal in depthness to the royal blue, may be given by employing cochineal instead of archil.

362. A blue of little durability is communicated to silk by means of verdigris and logwood. Bertollet says, that this dye might be rendered more lasting, by first giving it a lighter shade than is intended, in a bath of this kind, afterwards dipping it in an archil bath, and, lastly, in the indigo vat.

363. To dye raw silk blue, which is naturally white should be chosen. It ought to be thoroughly soaked in water, and afterwards put into the vat in separate hanks, as already mentioned with respect to scoured silk. If raw silk is to be dyed of the deeper shades of blue, it must also be treated in the same manner. The mode of applying the Prussian blue to silk is the same as the process already described for dyeing it upon wool: in both cases, the dye is very feebly united with the stuff.

III. Processes for Dyeing Cotton and Linen Blue.

364. The vat for dyeing cotton and linen blue, is, according to Pileur d'Apligny, a cask containing about 120 gallons. The quantity of indigo used is generally from six to eight pounds, which, after being pounded, is boiled in a ley, drawn off clear from a quantity of lime equal to the indigo, and double its weight of potash. The boiling is continued till the indigo is thoroughly penetrated by the ley, carefully stirring it all the while, to prevent the indigo adhering to the bottom, and being burnt.

365. Whilst the indigo is boiling, an equal weight of quicklime is slaked; about twenty quarts of warm water are added, and in this is dissolved as much green vitriol or sulphate of iron, as is equal to twice the weight of the lime. When the solution is completed, the liquor is to be poured into the vat, which must be previously half filled with water. To this the solution of the indigo must be added, with the remainder of the ley not used in boiling it. When all these are put into the vat, it is filled up to within two or three fingers of the brim, and stirred with the rake two or three times a-day, till it is in a state fit for dyeing, which it will be in about forty-eight hours, sometimes sooner, according to the temperature of the atmosphere.

366. A simpler process is followed at Rouen, which is thus described by Quatremer. "The vats are constructed of a kind of flint, covered, within and without, with a coating of fine cement. Every dye-house is furnished with a certain number of these, arranged in parallel lines. Each vat is capable of containing four hogsheads of water, and into it may be put eighteen or twenty pounds of indigo. The indigo having been macerated for a week in a caustic ley sufficiently strong to bear an egg, and then ground in a mill, in which not unfrequently the maceration is made, about three hogsheads and a half of water are put into the vat, and afterwards twenty pounds of lime. When the lime is thoroughly slaked, the vat is raked, and thirty-six pounds of sulphate of iron are put in. When the solution is completed, the ground indigo is poured through a sieve. On that day it is raked seven or eight times; and, after having stood at rest six-and-thirty hours, it is fit for dyeing.

367. In dyeing-establishments upon a large scale, vats are set or prepared at different times. The cotton or thread is first dipped in the bath which has been previously most exhausted; and then carried from vat to vat, till it attains the proper shade. It ought to be wetted before it is put into the first vat, and should not be left in the bath more than five minutes, as, in that time, it imbibs all the colouring matter it can take up. As soon as the dyeing in one vat is finished, the bath should be raked, and not used again till it has stood at least twenty-four hours; but if it has been freshly prepared, it need not stand so long.

368. When a vat has been used three or four times, it begins to change; no more veins appear on the surface after raking, or it becomes black. It must then be refreshed; and, for this purpose, four pounds of sulphate of iron, with two of quicklime, are added, and it is raked twice. A vat may thus be refreshed three or four times, diminishing the ingredients each time, as it declines in strength and quality.

369. Haussman describes a bath in which a much smaller proportion of indigo is employed. For three thousand pounds of water, he takes thirty-six pounds of quicklime, which he slakes in two hundred pounds of water; with this he mixes the indigo, well ground: in it dissolves thirty pounds of sulphate of iron in a hundred-and-twenty pounds of hot water; and, having left the whole at rest for a quarter of an hour, he finishes the filling of the vat, gently stirring it, without intermission. The blue vat, he observes, may be made at discretion, by varying the quantity of indigo. From twelve to twenty pounds may be taken for the quantity of water above directed, or even more, if a colour like that of indigo in substance be required, particularly when it is for dyeing linen. When the vat begins to grow turbid, dyeing in it must be discontinued; it must then be stirred, and left till the liquor above the sediment become clear. If the lime ceases to operate, from being saturated with carbone acid, a fresh portion of it must be added after being slaked in a sufficient quantity of water. If the iron be too much oxidated to act on the indigo, sulphate of iron is to be added, always taking care that there be more lime than is necessary to saturate the sulphuric acid, the excess being necessary to dissolve the indigo. When the indigo is exhausted, all that is requisite, is to add a fresh portion ground in water, to stir the vat repeatedly, and
Processes of Dyeing.

By observing these precautions, M. Haussmann preserved the same vat in a state fit for dyeing during two years; and he might have kept it still longer, had it not been for the accumulation of sediment, which at last rendered it impracticable to dip the stuffs sufficiently deep in the bath.

Bergman mentions another vat, which answers very well for dyeing thread or cotton. The following is the process, as described by Scheffer: To very strong soap-boiler's ley, indigo well powdered is added, in the proportion of three drachms to a quart; and after five minutes, when the colouring matter is well penetrated by the ley, six drams of powdered orpiment are added. The bath is then well raked. In a few minutes it becomes green, and exhibits the blue flower at the top, when the fire is extinguished, and the dyeing process begun.

371. Cotton and linen take very pale shades from Saxon blue; but Prussian blue may be applied more successfully to these stuffs, by the processes already described, than to wool or silk.

CHAP. V.

Processes for Dyeing Compound Colours.

372. Compound colours, in dyeing, are such as are formed from various modifications of the simple colours, whether by admixture or superinduction. If the processes by which these modifications are effected were of a mechanical nature, the resulting colour arising from the combination of particular colours might be pretty accurately determined; but the chemical action of the morant, employed in dyeing one colour, exerting its influence upon the mixed or superinduced colouring matter employed in dyeing another, produces effects which, in most cases, can only be ascertained by observation and experiment. Trusting, therefore, but little to the deductions of theory, our attention must be principally directed to the effects of the chemical agents we employ.

373. Pure or unmixed colours are rarely found in nature; and, indeed, in the preceding part of this article, we have described processes for dyeing colours, many of which were, strictly speaking, of a compound nature. Thus, red is almost uniformly found intermingled with yellow, scarlet, and madder colours, being composed of these principles; and indigo, which appears to furnish the most perfect blue, is always debased by a certain admixture of yellow. We did not consider these deviations, however, from the simple colours which we have already discussed, as a sufficient reason for separating processes nearly connected with each other, and which scarcely admit of any systematic arrangement that is altogether free from objection. The compound colours are as unlimited as the combinations of simple colours, by means of which they are formed. We can only consider, however, the principal mixtures; and these may be comprehended under the following classes.

1st. A mixture of blue and yellow, which produces all the intermediate shades between the yellowish-green, and the dark green verging to black.

2d. A mixture of red and blue, which comprehends all the shades from a deep violet colour to a blue.

3d. A mixture of red and yellow, which embraces all the shades from a scarlet colour to that of musk and tobacco.

Class I. Processes for Dyeing Mixtures of Blue and Yellow, or Green.

374. Several plants are capable of affording green colours, but the dyes which they communicate are all of a fading nature. D'Ambourne, indeed, asserts, that he had a permanent green from the fermented juice of the berries of the berry-bearing alder, by preparing the cloth with tartar, nitrous solution of bismuth, and common salt, and adding to the fermented juice of the berries, when warmed, a little acetic of lead. The cloth acquired in this bath a middle shade, between parrot and grass green. Green is obtained by the dyers from an admixture of blue and yellow, either of these colours being first applied, and then the other. It is usual, however, to apply the blue dye first, and afterwards the yellow. The pastel vat is commonly employed; but for some kinds of green, the solution of indigo in the sulphuric acid is used. In the latter case, the blue and yellow are either dyed separately, or all the ingredients are mixed together to dye by a single operation. Sometimes greens are produced by employing solutions of copper with yellow substances.

1. Processes for Dyeing Wool Green.

375. The blue ground, which is usually applied first, ought to be proportioned in intensity to the deepness of the green we wish to obtain: Thus for the green like that of a drake's neck, a ground of deep royal blue is given; for parrot green, a ground of sky blue, &c. The cloths having received the proper ground, they are washed in the fulling-mill, and then boiled as for common welding; but for the lighter shades, a smaller quantity of salts is used. In general, the cloths which are to have the lighter shades are boiled first; and when these are taken out, tartar and alum are added; and this practice is pursued until we come to the cloths intended for the darker shades, more and more tartar and alum being successively added.

376. The process of welding is conducted in the same manner as formerly described for dyeing yellow, with this difference, that a larger quantity of weld is employed, unless for the light shades, where the proportion is rather diminished. Frequently, a succession of shades, from the deepest to the lightest, is dyed at the same time, beginning with the deepest, and proceeding to the lightest. Between each dip, which lasts from half an hour to three quarters, water is added to the bath. Some dyers give each parcel two dips, beginning the first with the deep shades, and the second with the light ones. In that case, each parcel should remain a shorter time in the bath, which should never be allowed to reach the boiling point for the lighter shades. Deep greens are browned with logwood, and a little sulphate of iron.

377. The green obtained by means of solutions of indigo in sulphuric acid, known by the name of Saxon green, is more beautiful than the green procured by the preceding process, but it has less durability. According to a description of the process published in 1750, by the French government, the cloth for this dye is boiled for half an hour with alum and tartar, and then taken out and aired, without being washed. The bath is next to be cooled, and the solution of indigo well mixed with it, adding at first only one-half; the cloth is then put in and turned rapidly, without boiling, for five or six minutes; it is then taken out, that the remainder of the
solution may be added, which ought to be mixed with great care. After having gently boiled the cloth in it for seven or eight minutes, it is taken out and cooled; the bath is emptied to about three-fourths, perhaps somewhat more or less, according to the shade of green to be produced; it is then filled with a decoction of fustic, and when this bath is very hot, the cloth which had been dyed blue, and cooled, is dipped into it, until it has acquired the proper shade.

378. The following process, which is more simple, is described by Berthollet. A boiling is first given as for welding; and the cloth, being afterwards washed, fustic in chips inclosed in a bag is put into the same bath, and boiled for an hour and a half; it is then taken out, and the bath cooled to a temperature which the hand can support. Nearly a pound and a quarter of the solution of indigo, for each piece of cloth of eighteen ells to be dyed, is then added; at first it is to be turned rapidly, and afterwards slowly; the cloth is to be taken out before the bath boils. It is proper to put in only two-thirds of the solution at first, to take out the cloth after two or three minutes, and then to add the last third; the colour is thus rendered more uniform. If it is observed, that the colour does not take well, a little calcined alum reduced to powder is added. The Saxony-apple-green is dyed in the bath in which has served for Saxony green, after one-third or one-half of it has been taken out, and after it has been cooled. The cloth is turned in it until it is near boiling.

379. Woollen stuffs, which have previously been dyed blue in the common indigo vat, may also receive any of the various shades of green, which are usually communicated in this way from weld, by boiling them in water with about one-eighth part of their weight of alum, and afterwards dyeing them, without with about the same proportion of quercitron bark, and a little chalk added towards the end of the process. A beautiful Saxony green may be obtained from quercitron, by the following process, recommended by Dr Bancroft. The cloth having previously received the Saxony blue, should afterwards be well rinsed, to separate, as far as water will do it, the acid imbibed in combination with the indigo, and which has a strong tendency to throw down and weaken the quercitron, as well as the weld yellows. To counteract more effectually the operation of the acid, it will be proper to add about three pounds of chalk, with ten or twelve pounds of alum, for the preparation of a hundred pounds weight of cloth, which is to be turned and boiled, as usual, for about an hour; and then, without changing the liquor, ten or twelve pounds of bark, powdered and tied up in a bag, may be put into it, and the dyeing continued, taking care frequently to agitate the bag, in order that the colour of the bark may spread equally through the liquor. It will be found, however, that the yellow will manifest itself but slowly in this way, by reason of the sulphuric acid imbibed with the blue colour, joined to that of the alum in the preparation liquor, which the portion of chalk before mentioned will not have been sufficient to overcome; and therefore when the dyeing with bark has continued about 15 minutes, it will be proper to add another pound of clean powdered chalk, stirring it well through the liquor, and to repeat this addition afterwards, once, twice, and even three times, at intervals of six or eight minutes, if the colour does not rise sufficiently without it. By these additions, says Dr Bancroft, the quercitron yellow will manifest and apply itself abundantly and equally, so as to produce very beautifully greens, which, by varying the proportions of indigo, as well as of bark and alum, may be varied at pleasure. The chalk in this case does not merely answer the purpose of separating the acid left in the cloth, by the sulphate of indigo and the alum; but by uniting with this acid, it becomes a sulphate of lime, and fixes itself, in part at least, as a basis in the fibres of the cloth, where it helps to raise the colour, and also to render it a little more durable. At present the Saxony greens are commonly dyed with the old fustic, because the colour of this wood is not thrown down by acids, so much as that of the bark and weld, and this difference enables the dyer, when he has extracted the fustic colour by previous boiling, to mix the sulphate of indigo with it, and dye the cloth green by one operation, after it has been prepared as usual with alum and tartar. The process, however, which Dr Bancroft has described for doing this with bark, is fully as cheap and expedient, and the green produced will be more beautiful, because the quercitron yellow is more bright and clear than that of fustic, See Phil. Trans. Col. 135.

380. Dr Bancroft has described another process, by which beautiful Saxony greens may be produced, cheaply and expeditiously, by combining the yellow of quercitron, the murio-sulphate of tin and alum, with the sulphate of indigo. "To produce this combination most advantageously, (says he,) the dyer, for a full bodied green, should put into the dyeing vessel after the rate of six or eight pounds of powdered bark, (in a bag) for every hundred pounds weight of cloth, with only a small proportion of water, as soon as it begins to grow warm; and when it begins to boil, he should add about six pounds of murio-sulphate of tin, (with the usual precautions,) and a few minutes after about four pounds of alum; these having boiled together five or six minutes, cold water should be added, and the fire diminished so as to bring the heat of the liquor nearly down to what the hand is able to bear; and immediately after this, as much sulphate of indigo is to be added as will suffice to produce the shade of green intended to be dyed, taking care to mix it thoroughly with the dyeing liquor by stirring, &c; and this being done, the cloth, previously scoured and moistened, should be expeditiously put into the liquor, and turned very briskly through it for a quarter of an hour, in order that the colour may apply itself equally to every part, which it will certainly do in this way with proper care. By these means, very full, even, and beautiful greens, may generally be dyed in half an hour; and during this space, it is best to keep the liquor at rather less than a boiling heat. Murio-sulphate of tin is infinitely preferable, for this use, to the dyers' spirit; because the latter consists chiefly of nitric acid, which, by its highly injurious action upon indigo, would render that part of the green colour very fugitive, as I have found by repeated trials. But no such effect can result from the murio-sulphate of tin, since the muriatic acid has no action upon indigo, and the sulphuric is that acid which alone is proper to dissolve it for this use. Respecting the beauty of the colour thus produced, those who are acquainted with the unequalled lustre and brightness of the quercitron yellows dyed with the tin basis, must necessarily conclude, that the greens composed therewith, will prove infinitely superior to any which can result from the dull muddy yellow of old fustic: and in point of expense, it is certain that the bark, murio-sulphate of tin, and alum, necessary

Advantages of this process.

Another process still more advantageous.
to dye a given quantity of cloth in this way, will cost less than the much greater quantity (six or eight times more) of fustic, with the alum necessary for dyeing it in the common way; the sulphate of indigo being the same in both cases. But in dyeing with the bark, the vessel is only to be filled and heated once; and the cloth, without any previous preparation, may be completely dyed in half an hour; whilst, in the common way of producing Saxon greens, the copper is to be twice filled; and to this must be joined the fuel and labour of an hour and a half's boiling and turning the cloth in the course of preparation, besides nearly as much boiling in another vessel, to extract the colour of the fustic; and, after all, the dyeing process remains to be performed, which will be equal in time and trouble to the whole of the process for producing a Saxon green with the bark; so that this colour obtained from bark will not only prove superior in beauty, but in cheapness, to that dyed as usual with old fustic." See Phil. of Perm. Col. vol. ii. p. 136.

381. When silk is to be dyed green, the process of scouring is the same as for other colours; but when the lighter shades are to be applied, that operation must be performed as effectually as for blue. The dyeing process is managed a little differently from that of woollen stuffs. The silk, after being well alumed, is slightly washed at the river, and divided into small hanks, that it may receive the dye as equally as possible, it being extremely difficult to prevent the green being spotted or striped. It is then put into the weld bath, and carefully turned. After the ground is thought sufficient deep, a pattern is tried in the vat, to ascertain if the colour has acquired the proper shade; if not, decoction of weld is added until this is the case. The silk is then taken out of the bath, washed, and dipped in the vat as for blue. To deepen and vary the hue, decoction of logwood, fustic, or annotta, are sometimes added to the yellow bath, after the weld has been taken out or exhausted; and for the very light shades, such as apple and sea-green, a much weaker ground is given. Yellow baths, which have been already used, answer best for the delicate shades, as the silk takes the colour from these more slowly and uniformly.

382. When the blue vat is employed to dye green, saw-wort (159) may be substituted for weld; it is even preferable, because its yellow is naturally of a greenish cast; dyers' brown may also be used, and sometimes these substances are mixed together. Other substances, affording a yellow colouring matter, may be employed for the same purpose, and particularly quercitron, which affords so many beautiful shades of yellow.

383. Saxon green may be communicated to silk, according to Guldiche, by three yellow substances, turmeric, fustic, and French berries; and to these may be added quercitron. The greens obtained by means of turmeric are the most beautiful and delicate, but they are also the most fading. The silk is alumed in the proportion of four ounces of alum to the pound; and left twelve hours in the solution when cold. A bath is prepared with an ounce of pounded turmeric, to which as much sulphate of indigo as will give it a sufficiently green colour is added; an ounce of solution of tin is then mixed with it, and the alumed silk dipped until it has acquired a fine green colour. It is then wrung, washed, and dried in the shade. When fustic is used, the yellowing is conducted in the same manner as with weld. If the tincture of French berries in aceto-citric acid be employed, half the quantity of alum may be taken that has been recommended for turmeric; in other respects, the process is the same.

384. Dr Bancroft gives the following simple process for producing, with quercitron, Saxon greens by one operation. Boil, after the rate of four pounds of quercitron bark with three pounds of alum, and two pounds of muriro-sulphate of tin, in a suitable quantity of water, for ten or fifteen minutes; when the heat of the liquor is afterwards reduced, so that the hand can bear it, put in the silk, and retain it a proper time in the bath, taking care, however, to agitate the liquor constantly, that the colouring matter, which would otherwise subside, may be kept equally diffused. By adding suitable proportions of sulphate of indigo to this yellow liquor, and keeping it well stirred, various and beautiful shades of Saxon green may be dyed in the same way, of a uniform shade, and at a small expense. The shades intended to incline most to the yellow should be first dyed, and afterwards, by adding more sulphate of indigo, those partaking more of the blue may be readily produced; and, indeed, says Dr Bancroft, nothing can be more commodious or certain, than this way of dyeing the most beautiful Saxon greens upon silk. See Phil. of Perm. Col. vol. ii. p. 147.

385. A dye called English green, which unites the beauty of Saxon with the durability of common green, is sometimes applied to silks. In order to give this green, Guldiche first gives the silk a light blue in the cold vat, soaks it in warm water, and washes it in a stream; he then dips it in a weak solution of alum, prepares a bath with the sulphate of indigo, an ounce of solution of tin, and the tincture of French berries. In this bath the silk is kept till it has taken the desired shade of green, when it is washed and dried in a shady place. The shades are rendered more or less blue or yellow, by the proportions of the ingredients by which these colours are communicated. When a goaling green is to be given to silk, it is first dyed of a light blue, green, then passed through hot water, and washed in a stream; lastly, while still moist, it is dipped in an annotta bath.

111. Processes for Dyeing Cotton and Linen, Green.

386. When cotton or linen is to be dyed green, a ground of ground of blue is commonly applied first, the stuffs being previously been properly secured. The proportion of yellow is regulated by the shade of colour to be given; and so also is the previous ground of blue. Pileur de Aplegny has described a process for dyeing cotton, or skeins of cotton, of a sea or apple green, Sea or apple green, in a single bath. For this process, verdigris is mixed green with vinegar, and the mixture kept well stopped fifteen days in a stone; four hours before using it, a solution of potash, equal in weight to that of the verdigris, is added, and the mixture is kept hot. The cotton thread or velvet are prepared, by being soaked in a warm solution of alum, made in the proportion of one ounce of salt, and five quarts of water, to the pound; they are then taken out, and the verdigris mixture added to the bath, into which they are returned, in order to be dyed.

387. To dye beautiful greens upon cotton, Chapital Chapital's has recommended that it be first dyed of a sky-blue process colour, by means of indigo dissolved by potash and orpinment, and afterwards macerated in a strong decoction of sumach; it is then to be dried and soaked in
the acetate of alumine; dried again, rinsed, and finally dyed with quercitron bark, employing twelve pounds of the latter to fifty pounds of cotton.

387. The various shades of olive green, and drake's neck green, are given to thread after it has received a blue ground, by galling it, and dipping it in a weaker or stronger bath of the acetate of iron, then in the weld bath with verdigrise; and lastly, in the bath with sulphate of copper. After the dyeing process is finished, the colour is brightened with soap.

388. In describing the processes of dyeing by means of Prussian blue, we described a method of applying that colouring matter to cloth, which had been suggested by Dr Bancroft: he also ascertained that if, instead of dyeing the cloth with weal or quercitron bark, and sulphate of iron only, he used alum along with the latter, an olive was produced; and this being soaked, as before mentioned, in warm diluted prussiate of potash (neutralized with sulphuric acid), it produced a beautiful green; the alum and quercitron bark or weal furnishing a sufficient quantity of yellow for that purpose, and the Prussian blue, by its superior brightness, giving the green an increased lustre. It is unnecessary to mention, that this green would be instantly tarnished, and at last decomposed entirely by soap.

CLASS II. Processes for Dyeing Mixtures of Red and Blue.

390. By various mixtures of red and blue, we obtain violet, purple, dove-colour, pansy, amaranth, lilac, and a great number of other shades, determined by the nature and proportion of the colouring matters used in the production of the simple colours, and the mordants employed to give them fixity, or heighten their lustre.

1. Processes for Dyeing Wool, Violet, Purple, &c.

391. According to the observations of Hellot, stuffs which have previously received the scarlet dye, take an unequal colour when blue is superadded. The blue is, therefore, given first, which even for violet and purple ought not to be deeper than the shade distinguished by the name of sky-blue. After a boiling has been given with alum, mixed with two-fifths of tartar, the stuff is dipped in a bath, composed of nearly two-thirds as much cochineal as for scarlet, to which tartar is always added. The only circumstance in which the process for dyeing purple differs from that for dyeing violet, is, that for the former a lighter blue ground is given, and a larger proportion of cochineal. Lilacs, and other light shades of the same kind, may be produced, by employing these means more sparingly, or by using the baths which have already been employed for dyeing full violets and purple. A little solution of tin is added, for some reddish shades, such as peach-blossom.

392. Perrner has recommended the sulphate of indigo, instead of the indigo vat, as producing a brighter blue, for the basis of purple and violet, and that too by a shorter and less expensive process. The colours obtained in this way are, indeed, not so durable as when the blue vat is employed; but Perrner asserts that their durability may be increased by the addition of alkali to the solution of indigo. He accordingly prepares a pound of cloth, with three ounces of alum, by boiling it for an hour, and half, and leaving it for a night in the liquor after it is cold. He makes the bath with an ounce and a half of cochineal, and two ounces of tartar, boiling it for three quarters of an hour, and then adding two ounces of solution of indigo, he stirs, and makes it boil gently for a quarter of an hour. He thus obtains a very beautiful violet. Other shades, resulting from the mixture of red and blue, are obtained, by increasing or diminishing the proportion of solution of indigo. He increases it as far as five ounces, and diminishes it to five draughts for each pound of cloth; he also reduces the quantity of cochineal, but never below an ounce, as the colour would then become too dull; he changes the proportion of tartar; and, lastly, he varies the preparation given to the cloth, by the addition of tartar, or solution of tin in different proportions.

393. With respect to these processes, it is justly remarked by Dr Bancroft, that the cochineal colour will only be united to the aluminous, and not to the tin basis; and, consequently, that they can only produce a crimson, of much less vivacity than the rose colour, which it would afford with a nitro-murrain of tin. But this latter mordant has always been avoided in dyeing purple and violet with indigo, on account, of the injurious effects which it produces on the colouring matter of that substance. The same objection does not apply to the muri-sulphate of tin, as the muriatic acid has no effect upon indigo, nor even the sulphuric in the very diluted state in which it is used in that mordant. Dr Bancroft has, therefore, very happily introduced the use of the muri-sulphate of tin with cochineal and the sulphate of indigo, for dyeing the colours in question, and produced violets and purples of greater beauty and vivacity, than can be obtained by the preceding processes. See Phil. of Permac. Col. vol. ii. p. 383.

394. Logwood is sometimes employed to communicate to wool, sloe, damascene, purple, and other shades, which may be considered as modifications of red and blue. This wood, with the addition of galls, readily affords all these colours to wool; but they possess little stability. Decoruzille, a well-informed dyer in France, has, however, disclosed a process to Berthollet, by which he succeeded in obtaining, from logwood, a very good and durable dye. The mordant he first employed was composed of solution of tin, muriate of soda, (common salt,) acullus tartarite of potash, (cream of tartar,) and sulphate of copper. He afterwards learned a better way of preparing it from M. Gros, who formed it by dissolving the tin in a mixture of sulphuric acid and sea salt, with a suitable portion of water, to which the tartarite of potash and sulphate of copper were added afterwards. Wool, in the fleece, was dyed with this mordant, by employing the latter in the proportion of one-third of the weight of the stuff; but for cloth, one fifth was deemed sufficient. A bath was prepared of a temperature which the hand could bear, with which the mordant was well mixed. The wool was then dipped in it and duly stirred, the same degree of heat being kept up for two hours, and even increased a little. The cloth was then taken out, aired, and well washed. A fresh bath of pure water was then prepared, to which a sufficient quantity of the decoction of logwood was added. The stuff was again immersed, stirred, and the bath raised to a boiling heat, which was continued for a quarter of an hour. The stuff was then taken out, carefully rinsed, and dried, which finished the process. When a portion of Brazil wood was added, the shade partook more of the red, and afforded the colour known in France by the name of prune de Monsieur.
II. Processes for Dyeing Silk, Violet, Purple, &c.

395. In dyeing silk, two kinds of violets are distinguished, the fine and the false. To produce the fine violet, the silk is first passed through a bath of cochineal, and afterwards dipped into the indigo vat. More or less cochineal is used, according to the depth of the desired shade; but neither tartar nor solution of tin form parts of the mordant, which consists of alum only. The usual proportion of cochineal for a fine violet is two ounces for each pound of silk. When the silk is dyed, it is washed at the river, and beaten twice. It is then dipped in an indigo vat, of greater or less strength, according to the depth we wish to give the violet. It is then washed, and carefully dried. To give greater beauty and strength to the colour, it is commonly passed through the archil bath; a practice which, as Berthollet observes, though frequently abused, is indispensable for the light shades, the colour of which would otherwise be too dull.

396. When the silk is intended to be dyed purple, a very light blue shade must be given to it, after receiving the cochineal dye. The deepest shades must be dipped in a very weak vat, and those which are lighter, in cold water, with which a little of the liquor of the vat has been mixed. The light shades of this colour, such as gillyflower, gridelin, peach-blossom, &c. are obtained by reducing the proportion of cochineal.

397. The false violets are given to silk in various ways, but the most beautiful are usually communicated by archil, the strength of the bath being adapted to the colour we wish to produce. After being scoured and beaten at the river, the silk is introduced into the bath, and turned in it on skin sticks. When the colour is supposed to have sufficiently taken, a pattern is tried in the indigo vat, to ascertain if it acquires the desired shade of violet; and after the shade is found to be of the proper depth, the silk is beaten at the river, and dipped in the vat, in the same manner as for the fine violets.

398. A violet is given to silk, by dipping it in water containing a solution of verdigris, without alumming it, and then giving it a bath of logwood. The blue colour which it assumes in the bath is changed to violet, either by the addition of alum while it remains there, or by passing it, after being taken out, through a weaker or stronger solution of that substance. This violet possesses neither durability nor beauty. A better violet may be communicated, by passing alummed silk first through a bath of Brazil wood, and again, after it has been washed at the river, through a bath of archil.

III. Processes for Dyeing Cotton or Linen, Violet, Purple, &c.

399. Cotton is usually dyed violet, by first giving it a blue ground in the vat, suited to the proposed deepness of shade, and then drying it. After being left for twelve or fifteen hours in a gall bath, prepared in the proportion of three ounces of galls to a pound of the stuff, it is again wrung and dried. It is next passed through a decoction of logwood, from which, after being well soaked, it is taken out, when two drachms of alum and one drachm of dissolved verdigris for every pound of cotton, are added to the bath. It is then redipped on the skin sticks, and turned for a full quarter of an hour, after which it is taken out and aired. This being done, it is once more immersed in the bath for a quarter of an hour, and then taken out and wrung. The dyeing is completed by introducing the cotton into a fresh bath of logwood, to which two drachms of alum are added, and retaining till it acquires the desired shade.

400. Violets and purples, extremely durable, may be communicated to cotton prepared and dyed as for the Turkey red, with this difference, that to the alum-steep or mordant, a greater or less portion of sulphate of iron is added, according as the colour is wished to incline more or less to a dark shade. Cotton which has received a light indigo blue, may also be rendered purple or violet, by impregnating it with the aluminous basis, and dyeing it with madder.

401. A good and durable violet, may also be applied to cotton or thread by the following process: The cotton to be dyed is macerated in a decoction of galls, (employing one pound of the latter to six pounds of the former,) then dried, and afterwards soaked in a saturated solution of equal parts of alum and sulphate of iron; it is then rinsed, dried, and afterwards dyed with its weight of madder. The colour, which is durable, may be made to incline more or less to the purple or violet, by varying the proportions of alum and sulphate of iron. An acetate or pyroglignite of iron may be advantageously substituted for the sulphate.

Class III. Processes for Dyeing Mixtures of Red and Yellow.

402. An infinite variety of shades may be obtained from the combination of red and yellow, by altering the proportions of the ingredients which afford these colours, and varying the mordants employed in the dye bath. Pernier also describes a great number of varieties of the same kind, which he produced by using different yellow dyes, and by employing in the preparation of the stuff in the bath, tartar, alum, sulphate of zinc, or sulphate of copper. The principal colour resulting from this combination is orange.

II. Processes for Dyeing Wool, Orange, &c.

403. By boiling fustic in a scarlet bath, and heightening it by a small portion of cream of tartar and the solution of tin, we may produce successively a pomegranate, orange, a jonquille, &c. Quercitron may be substituted for fustic, and both must be used in proportion to the shade required. The addition of a little madder will produce a gold colour. If, in place of bright yellows, we employ colouring matters of a brownish cast, such as the greater number of astringents, we shall obtain less brilliant but more solid colours: thus hazel roots, walnut peels, sumach, &c. yield tobacco, chestnut, musk colours, &c.

II. Processes for Dyeing Silk, Orange, &c.

404. In describing the processes for dyeing silk yellow, we noticed various methods of giving it an orange cast. Marrones, cinnamon, and all the intermediate shades, are communicnted to silk by various proportions of logwood, Brazil wood, and fustic. The silk having been scoured as usual, and alummed, is put into a bath prepared by mixing decoctions of these woods, according to the desired shade, but causing the fustic to predominate. The silk is turned in the bath in the usual way, and afterwards introduced into a fresh bath of the same.
DYEING.

269

Processes of Dyeing.

Ingredients, if necessary. Brick colours are given by dipping the silk, prepared with solution of galls, mixed with a certain quantity of solution of iron, in an annato bath.

III. Processes for Dyeing Cotton or Linen, Orange, &c.

405. For the different shades of marrone, cotton is galled, and then dipped, and worked in the usual manner, in a bath to which more or less of the pyrolytine of iron has been added; it is then washed in a bath, with which verdigrise has been mixed, welded, and dyed in a bath of fustic, to which a solution of soda and alum are sometimes added. After the cotton thus prepared has been completely washed, it is well muddled, then dipped in a weak solution of sulphate of copper, and, lastly, in soap-suds.

Cinnamon and mor-dore colours.

406. Cinnamon and mor-dore colours are given by dyeing them first with verdigrise and weld; they are then dipped in a solution of sulphate or acetate of iron, wrung, and dried. When dry, they are galled, in the proportion of three ounces of galls to the pound of stuff, dried again, alumed as for red, and muddled. When dyed and washed, they are put into very warm soap-suds, and turned until they are sufficiently bright. Decoration of fustic is sometimes added in the aluming.

407. According to M. le Piaire d'Apligny, a fine olive may be communicated to thread and cotton, by boiling separately four parts of weld with one of potash, in a sufficient quantity of water, and Brazil-wood which has steeped over night with a little verdigris, and then mixing the two solutions in different proportions, according to the shade required, as a dyeing bath. The cotton and thread are then dipped in it, in the usual way.

CHAP. V.

Processes for Dyeing Black.

408. The appearance called black, consisting strictly in the absence of all colour, the processes for producing it upon stuffs could not with propriety be introduced either under simple or compound colours; it ought to be remarked, however, that the dyer is but little influenced by the prismatic distinctions, and regards as a colour every palatable change produced on the appearance of stuffs by the union of vegetable matter. Black is therefore usually treated, by the writers on dyeing, as a simple colour; but with no great propriety, for though this appearance may certainly be communicated to stuffs by means of a mordant, and a single vegetable colouring matter, the most beautiful and perfect blacks are given by a combination of several colours. These considerations have induced us to allot to it a separate Chapter, and to give the processes for dyeing black, after having described the methods of applying colours, properly so called. At the same time, that we may not increase to an unnecessary degree the subdivisions of this article, founded upon distinctions of colour, we shall annex the methods of dyeing such shades of colour as may be considered to be modifications of black with other colours.

409. Perhaps no substance in nature possesses the property of absorbing all the rays of light; and, accordingly, there can scarcely be said to be any colouring matter which is capable of dyeing, alone, a deep and permanent black. The juice of the cashew-nut communicates to linen a dark colour, but it cannot be called black. The same may be said of the anacardium occidentale, and several other plants, which produce similar effects. And, indeed, as Dr. Bancroft justly remarks, a substance which was perfectly black, and neither reflected nor transmitted a single ray of light, would be absolutely invisible, and incapable of exciting any sensation of colour whatever. What we commonly denominate black, therefore, does not result from a total absorption of the rays of light, but from a feeble reflection or transmission of those which are dark-coloured. Black may, accordingly, be produced upon stuffs by a condensation of such matters as reflect the dark rays most imperfectly, particularly blue and violet.

410. Several substances, both animal and vegetable, possess the property of forming very dark compounds with the oxide of iron, at a maximum of oxidation; this is the case with the prussic acid, and more especially with what is called the astringent principle. Blacks are, therefore, usually communicated to stuffs by means of the salts of iron, and the astringent principle. A ground of blue is generally given, before the application of the black dye, as then a less quantity of the ingredients is necessary to produce a deep tint, and the stuff is less apt to be injured by the ferruginous mordant. A ground of any other dark colour may be used instead of blue, but the black will be inferior in deepness and glossiness.

I. Processes for Dyeing Wool, Black, &c.

411. According to the process described by Heliot, Heliot's woolen cloth, which is to be dyed black, ought previously to receive a deep blue ground, to be washed in the river immediately after being taken out of the vat, and afterwards cleansed at the fulling-mill. For a hundred pounds of stuff, ten pounds of logwood, and an equal quantity of Allepo galls in powder, are put into a bag, and boiled for twelve hours in a copper, with sufficient quantity of water. One-third of this bath is transferred to another copper, with two pounds of verdigris, and into this the stuff is immersed, turning it continually for two hours, and keeping the bath very hot, without allowing it to boil. The stuff is then taken out, and a portion of the bath, equal to the former, is put into the copper, with eight pounds of sulphate of iron. While the sulphate of iron is dissolving, the fire is diminished, and the bath suffered to cool for half an hour; the stuff is again put in, moved well about for an hour, and again taken out to air. The remainder of the bath is now added, taking care to press the bag well, which contains the dyeing ingredients. Fifteen or twenty pounds of sunchine are also added; and the bath being brought just to the boiling point, the ebullition is instantly checked with a little cold water. Two pounds more of sulphate of iron are added, and the stuff is immersed for another hour. It is then taken out, washed, aired, and returned again to the copper for another hour, during which it is constantly stirred. Lastly, it is taken out, well washed at the river, and fulled. When the water comes off clear, another bath is prepared with weld, which is made to boil for a moment, and, after being cooled, the stuff is passed through it, to soften it, and give the black a better body.

412. Heliot describes another process, which is less tedious and complicated than the preceding, but it produces an inferior black. He recommends for fifteen ells of deep blue cloth, a bath composed of a pound and a
Dyeing.

half of yellow-wood (morus tinctoria), five pounds of logwood, and ten pounds of sumac. After boiling the cloth in this bath for three hours, it is taken out, when ten pounds of sulphate of iron are put into the copper, and the cloth is kept in it two hours longer: it is then aired, put into the bath again for another hour, and, lastly, washed and fulled.

418. Broad cloth may be made to acquire a black, in every respect unexceptionable, by boiling it two hours in a decoction previously prepared with about one-seventh of its weight of galls, and as much chiplog wood; afterwards passing it for another two hours through a solution of one-tenth of its weight of sulphate of iron, and keeping the solution at a scalding heat only. Most dyers are satisfied with a smaller proportion of galls, and supply the deficiency by increasing the quantity of logwood, and by adding also a portion of sumac.

414. For coarse stuffs, and cheap woollens, the blue ground from wood is omitted, its place being badly supplied by logwood and sulphate of copper or verdigrise; or the latter is dissolved with the sulphate of iron to convert a part of the colouring matter of the logwood into a kind of blue. Dr. Bancroft disapproves of this practice. He says, that the only use of the sulphate of copper, or verdigrise, is, to produce a logwood blue, which soon changes to a rusty brownish colour; and that it would be better to use the logwood with the sulphate of iron alone: (Phil. of Perm. Col. ii. 454.) He adds, that, with sulphate of iron and logwood, it is not difficult to produce a full and deep black, but that it is not so lasting as the black with sulphate of iron, and galls or sumac, either alone, or with a moderate proportion of logwood; which last certainly improves the appearance of the black dyed from galls and iron, by rendering it more intense, glossy, and soft. All black cloths, for the dyeing of which a large proportion of logwood has been used, are reddened by the application of muriatic acid; a little liquid ammonia restores the colour.

415. About the year 1733, Bergman strongly recommended a method of dyeing cloth black, by dipping woollens which had previously received a blue ground, in a bath composed of eight pounds of cream of tartar, sixteen pounds of sulphate of iron, two pounds of verdigrise, and ten pounds of wood, to a hundred pounds weight of cloth, and afterwards boiling it for two hours in a decoction of a hundred and fifty pounds of urush, or bear’s foot.

416. Dr. Bancroft states, that a fine lasting black may be dyed, without iron or any other basis, upon blue cloth, from a species of lichen, musca pulmonaria, (91.) and that, if this substance could be readily and copiously obtained, it would, probably, deserve to be preferred to madder and woad for rendering blue cloth black.

417. The proportions of ingredients for dyeing black, usually employed by the dyers of this country, are, for a hundred pounds of woollen cloth, dyed first a deep blue, about five pounds of sulphate of iron, the same quantity of galls, and thirty pounds of logwood. The cloth is first galled, and then passed through the decoction of logwood, to the sulphate of iron has been added. When the cloth is completely dyed, it is washed in a river, and full’d till the water comes off clear and colourless. Some recommend fine cloths to be full’d with soap-suds; but this operation requires an experienced workman to free the cloth perfectly from the soap. Many advise to give the cloth a dip in a bath of weld when it comes from the fulling-mill, which is said to soften, and fix the black.

418. To give a browning, the stuff which has been just dyed, is dipped in a solution of sulphate of iron, to which an astringent has been added. More frequently a small portion of solution of iron is mixed with a bath of water; and more is added, till the stuff dipped in it has attained the desired shade. Permnr frequently soaks the stuff in a solution of sulphate of iron; to which he sometimes adds other ingredients; and, when taken out of this mordant, he dips it in the dye bath. The first method is employed for marrones, coffee, damascene colours, and other shades of browns; a more or less deep colour being given them, according to the shade we wish to obtain by browning: a bath is then prepared of galls, sumac, and elder bark, with the addition of sulphate of iron. The stuffs intended for the lighter shades are dipped first; and, when they are finished, the browner ones are dipped; a quantity of sulphate of iron, proportionate to the end proposed, being added for each operation.

419. Dye colours, of various shades, are very conveniently and cheaply dyed, by the queretron-bark, and an iron basis. For this purpose, Dr. Bancroft recommends the bark to be boiled for a few minutes in a copper vessel, with one-third or one-fourth of its weight of sulphate of iron; and the liquor having been well mixed, and a little cooled, the cloth may be dyed in it as usual. To sadden and darken the colour still further, a little sumac may be employed with the bark. See Phil. of Perm. Col. ii. 144.

II. Processes for Dyeing Silk, Black, &c.

420. Silk which is intended to be dyed, is commonly galled by boiling four or five hours with a fifth of its weight of white soap, after which it is beetled and carefully washed. It is then galled, by leaving it from twelve to thirty-six hours in a decoction prepared with about three-fourths of its weight of galls, which have been boiled three or four hours; after which it is taken out, and washed in the river.

421. As silks are capable of combining with a greater or less quantity of the astringent principle, they receive, when dyed black, a greater or a less augmentation to their weight, not only from the astringent principle, but also from the oxide of iron which combines with it in like proportion. The dyeing process is, therefore, varied, according as the operator is desirous of rendering the silk more or less heavy. Hence the distinction of light and heavy blacks.

422. The difference in the process for obtaining heavy black, consists in leaving the silk a longer time in the decoction of galls, in repeating the galling, in dipping the silk in the dye a greater number of times, and leaving it longer in the bath each time.

423. Silk dyers usually preserve a vat for the black, Vat for and its composition, which generally consists of many superfluous ingredients, and varies greatly in different dye houses. The vat is frequently continued for many years, the black dye being always renewed when it is nearly exhausted. Macquier has given a description of one of these vats; it contained seeds of fenugreek, fen-wort, cimmin, colocynth, buckthorn berries, agric, nitre, ammoniac, sal gem, litharge, antimony, lead ore, opiment, corrosive muriate of mercury, together with a variety of other ingredients apparently added at random. Mac
Dyeing

It acknowledges, that many of these substances are useless; and, indeed, few of them are now employed. Iron filings are generally added to the dye-bath; but some dyers in France use in its stead the powder found in the trowths of cutlers' grindstones.

Dyeing process.

425. The bath for dyeing silk ought never to be allowed to boil. Gum and solution of iron are added to it; in different proportions, according to the various processes; and when it is observed that the gum is dissolved, and the liquor nearly boiling, it is allowed to settle for about an hour. The silk, being dipped in the bath, and managed in the usual way, is taken out when it has absorbed a sufficient quantity of the dye, wrung, and exposed to the action of the air, which deepens the black. After it has had three wringings, the bath is heated anew, fresh portions of gum and sulphate of iron being added as at first: the operation performed in the interval between two heatings is, in France, called a fire (un feu). The light black receives two fires, but the heavy requires three; and the silk is also allowed to remain in the bath for twelve hours after the last fire. When the dyeing is finished, the silk is rinsed in a vessel with cold water, by turning or shaking it.

426. The quantity of galls necessary for dyeing silk black, renders the process very expensive; and it is therefore an object of considerable importance, to find some method of diminishing their quantity. The following process has, for this purpose, been recommended by M. Anglès, who was a competitor for the prize proposed in 1776, by the Academy of Lyons, of which he was the object.

M. Anglès' process.

427. Silk carefully boiled and washed in the river, is to be immersed in a strong decoction of green walnut peels, and left in it till the colour of the bath is exhausted. It is then taken out, slightly wrung with the pin, dried, and washed in the river. The decoction of walnut peels is made by boiling a full quarter of an hour, when it is taken from the fire, and allowed to subside before dipping the silk, which has been previously immersed in warm water. A blue ground is next given, by means of logwood and verdigris. For every pound of silk, an ounce of verdigris is dissolved in cold water; the silk is left in this solution two hours; it is then dipped in a strong decoction of logwood, wrung out slightly, and dried before it is washed at the river. For light blacks, gelling may be altogether omitted; but to obtain a heavy black, half a pound of galls may be used for every pound of silk. To prepare the bath, two pounds of galls and three of sumach, are macerated in twenty-five gallons of water, over a slow fire, for twelve hours. After straining, three pounds of sulphate of iron, and as much gum-arabic, are dissolved in it. In this solution, the silk is dipped at two different times, leaving it in two hours each time, taking care to air it after the first dipping, and to dry it before giving it the second fire, when it is to be again aired and dried. It is then beetled twice at the river; after which a third fire is given it in the same manner as before, except that it is left in the bath four or five hours. When drained and dried, it is again beetled twice at the river. Care must be taken that the heat during the operation do not exceed 192° of Fahrenheit's thermometer; and before the last two fires, half a pound of sulphate of iron, and as much gum-arabic, must be added. For removing the harshness of the black, M. Anglès prefers the decoction of weld to the solution of soap.

428. M. Anglès asserts, that if silk be dyed blue with indigo, previous to its being dipped for black, it will take only a mealy colour; but that a velvet black will be obtained if it be prepared with logwood and verdigris. He says also that green walnut peels soften the silk. Though a fine black may be procured from green walnut peels, and the bath above described, he notwithstanding adds logwood and verdigris, that he may not be obliged to use a large quantity of sulphate of iron, which weakens the silk. Lastly, he thinks that galls serve only to give the silk weight, and that sumach is sufficient for the dye.

429. The Chinese are said to improve their black dye upon silk, by passing it, when dyed, through a bath containing one pound of starch, with half as much of the oil of linseed, or of rape or hempsed, for every five or six quarts of water. A great variety of shades are obtained by the mixture of Brazil-wood, logwood, archil, and galls, and by a burning with sulphate of iron; but all these shades, though they have a pleasing lustre, are apt to fade. It is rather by the eye, than by any particular rules, that the dyer is to be guided in communicating them.

III. Processes for Dyeing Cotton and Linen, Black, &c.

430. In order to dye cotton and linen black, a solution of iron is employed, which, in France, receives the name of the black vat. The solution, which is a kind of acetate of iron, resembling a preparation of that metal, described under the head of Mordants (94.), is formed with vinegar or small beer, or small wine made from grapes, after they have been pressed, by adding water to them; rye meal, or some other ingredient being added, to assist the acetylation. Pieces of old iron are thrown into this liquor, which is allowed to stand till wanted, but never used in less than six weeks, or two months. To this bath astringents are frequently added, particularly the decoction of alder bark, which of itself has the property of dissolving a considerable portion of oxide of iron.

431. The following method of dyeing cotton and linen, as practised at Rouen, is given by M. le Pileur, a dyer at Rouen.

Process for dyeing.

The stuff to be dyed is boiled for twenty-five minutes, using four ounces of galls to every pound of stuff; and leaving it twenty-four hours in the gall liquor, after which it is again wrung out and dried. About five quarts of the liquor of the black vat are required for every pound; and a pound are then poured into a tub, in which the thread is worked with the hand, bound by pound, about a quarter of an hour, when it is wrung out, and aired. This operation is twice repeated, adding each time a fresh supply of the black vat, which ought to be carefully scummed. It is then taken out, aired, wrung, washed at the river to cleanse it effectually, and dried. When this stuff is to be dyed, a pound of alder bark for every pound of the stuff is boiled for an hour in a sufficient quantity of water. About half the bath that served for the galling; and half as much sumach as alder bark is then added, and the whole boiled together for two hours, and then strained through a sieve. When the liquor is cold, the stuff is put in and carefully worked, airing it from time to time: it is then let down into the
DYEING.

Processes of Dyeing.

342. The Abbé Mazèes has described a process for dyeing cotton and linen black, by dyeing them with madder, having previously prepared them with the souchou of the Turkey red, galling them with myrobalans, and passing them through a mordant, composed of lime-water and verdigrise. The process is tedious and expensive, and, according to M. le Pileur d'Apligny, does not produce a better black than is obtained by the preceding method.

343. M. le Pileur d'Apligny mentions another method of giving black to cotton and linen, which he describes as very fine and durable. The stuff is first scoured as usual, galled, alummed, and afterwards dipped in the cold bath. When taken out of this bath, it is to be dyed in a decoction of logwood, to which a quarter of a pound of sulphate of copper has been added for every pound of stuff. After this, it is to be washed in the river, and wrung repeatedly, but not too hard. Finally, it is dyed in a madder bath, in the proportion of half a pound to each pound of stuff. See Essai sur les Moyens, &c. p. 168.

344. Guthlichs has described a solution of iron, which produces excellent effects in dyeing black. He directs to boil a pound of rice in twelve or fifteen quarts of water, till it is wholly dissolved; into this solution is to be thrown as much old iron nailed red hot, as will come half way up to the surface of the liquor. This is to be done in a vat exposed under cover to the air and light, at least a week. An equal quantity of red hot iron is thrown into as much warm vinegar as there was solution of rice in another vessel, and in like manner exposed to the air and light. After some days the contents of the two vessels are to be mixed together, and the mixture is to be left a week exposed to the open air. The liquor is then to be decanted, and preserved in a close vessel for use. To dye cotton and linen in this mixture, all that is necessary is to leave them in the liquor till they acquire a sufficient black, which will not be longer than twenty-four hours at most. If the liquor do not contain enough of ferruginous particles, the stuff, after being taken out, must be put into fresh portion. In this way, a fine and permanent black will be produced.

345. In all the processes we have described, the gallick, when that operation was employed, was always given first, and the solution of iron applied afterwards.

Dr Bancroft considers this practice to be extremely injudicious, and proposes to reverse the order of these operations, applying first the solution of iron as a mordant, and then that of the galls as a colouring matter. "It is nutritious," says he, "that calico-printers, when they wish to produce any of the colous produced by the aid of iron, or its oxide, as a basis, invariably begin by applying the basis, (commonly the acetate or pyrolyzite of iron, separately to the calico, superimposing the vegetable colouring matter, and preserve them an ounce of vegetable colouring matter; excepting only in those cases where a less permanent permanent black or other colour is applied, for which the basis or mordant is previously mixed and combined with the vegetable colouring matters. And it is well known, that the black and other colours given by calico-printers from sumach, madder, weld, quercitron bark, &c. upon an iron basis, applied first and separately, are much more lasting than the same colours produced in a different manner by the ordinary dyers." He afterwards concludes, "and I am confident, from the results of many experiments, that being so applied, there can be no difficulty afterwards in producing a full and permanent black by dyeing the linen or cotton, which has received this basis, with a suitable portion of galls, with or without an addition of sumach, and even without the co-operation of a blue ground from indigo, which is commonly thought necessary, at least for the finer and more costly cotton or linen goods intended to be made black." (Phil. of Perm. Col. vol. ii. p. 469.) These observations certainly deserve the attention of the practical dyer.

346. For black-gray, iron-gray, and slate-gray, cotton Grayz, and linen have a blue ground given them, but for another. All the shades require a galling proportionate to the grey to be produced. When the thread has been gallicd, wrung, and dried, it is dipped on the skain sticks in a tub of cold water, to which is added a proper quantity of the bath from the black vat, and of a decoction of logwood: the thread is worked in this pound by pound, washed, and dried.

347. M. le Pileur d'Apligny gives the two following processes for gray:

1st, The thread is gallicd, dipped in a very weak bath of the black vat; and then maddered.

2d, The thread is dipped in a very hot solution of tartar, wrung gently, and dried. It is then dyed in a decoction of logwood. After this operation, the thread appears black; but on working it attentively in warm soop-suds, the surplus of the dye is discharged, and it remains olive, pleasing and durable.

For calico-printing, see Topical Dyeing.

discovered by Dr Bancroft.
DYER, JOHN, an English poet of some note, was born in the year 1700, the second son of Robert Dyer of Aberglassney, in Caernarthenshire, an able and eminent solicitor. He was educated at Westminster school, under the care of Dr Freind, and was afterwards called home, to be instructed in his father's profession. But having little relish for legal pursuits, he, upon the death of his father, abandoned the study of the law; and, being fond of drawing, he became a pupil of the celebrated Richardson. After having studied for some time under this master, he wandered about South Wales, and the country adjacent, as an itinerant painter; and about the year 1727, he printed his first poetical production, Grongar Hill, in Lewis's Miscellany.

With the view of improving his talents as an artist, he undertook a journey to Italy; and upon his return to his native country in 1740, published the Ruins of Rome. Declining health, and love of study, afterwards induced him to enter into orders; and about the same time he married a lady of the name of Ensor, "whose grandmother," he says, "was a Shakespeare, descended from a brother of everybody's Shakespeare." He was fortunate enough to obtain several livings in the church, but did not long enjoy his ecclesiastical preferments. In 1757, he published his greatest poetical work, The Fleece; of which the following ludicrous anecdote has been transmitted. Dodsley, the bookseller, was one day mentioning it to a critical visitor with greater expectations of success than the other seemed disposed to admit. The author's age was asked; and being represented as advanced in life, He will, said the critic, be buried in woollen. He died in the year 1758.

Although neither the number nor the merit of Dyer's productions are sufficient to elevate him to the first rank among our English bards, yet he must ever be allowed a distinguished place in the list of our minor poets. Grongar Hill, according to the opinion of Dr Johnston, is the happiest of his effusions. But the well known antipathy of that celebrated critic to blank verse, seems to have rendered him blind to the merit of the other productions of Dyer; although he is forced to admit, that some passages are conceived with the mind of a poet. The title of the Ruins of Rome perhaps raises expectations which few poets are capable of gratifying; yet the poem of Dyer will be perused with a pleasure resulting at once from the sublimity of the subject, the grandeur of the conceptions, and the skilfulness of the versification. The Fleece, it must be admitted, is an unpromising subject for a poem, but Dyer has the merit of having given to it all the interest which the art of a poet could confer upon a barren topic. (2)
Dynamics.

Dynamics is that branch of Mechanical Philosophy which treats of the action of forces when they give rise to motion, and consists of the two following problems, viz.

1. From some of the circumstances which we observe in a motion, to determine the forces by which it is produced; and, 2. Conversely, from the knowledge which we have acquired of the forces, to determine all the circumstances of the motion to which they give rise.

It is customary, however, to give under Dynamics only the more general doctrines, and to reserve the rest for distinct articles. We shall, therefore, in this article, 1st, Give a short history of dynamics; 2dly, State some preliminary views with regard to the nature and measure of forces; 3dly, Lay down the general rules or laws according to which they act; 4thly, Deduce consequences with regard to their composition and resolution; and, 5thly, Apply these general doctrines to some of the most general cases of dynamics.

HISTORY.

The ancients were extremely little acquainted with dynamics. The wants of society, indeed, from the earliest times, required mechanical arts, and many of the Roman machines explained in Vitruvius excite our astonishment. But these inventions seem to have proceeded rather from numerous trials and natural sagacity, than from a proper acquaintance with the general principles of motion.

The ancients did not even know the first law of motion, and, instead of conceiving that the motion of a body was naturally uniform and rectilinear, they supposed that a circle, being the most perfect of figures, was that in which a body would naturally revolve. They cultivated both astronomy and geometry with considerable success; the former affording some of the finest examples of motion, and the latter furnishing the best assistance for the investigation of its properties; but they wanted our experimental method of inquiry.

Hence Aristotle, profound and accurate in most subjects, is extremely deficient when he treats of motion. Archimedes, it is true, who ranks at the head of ancient geometers as well as of ancient mechanicians, knew in some machines the true ratio of the power to the resistance in the case of equilibrium; but none of his writings discovers an acquaintance with the principle of the composition of forces, from which may be deduced the conditions of equilibrium in all machines, and still less does he appear to have been acquainted with the general method of calculating the motion of bodies, which forms the principal business of dynamics. In short, dynamics, as a science, is of modern date. The celebrated Galileo, about 200 years ago, laid the foundation of it. In his treatise on the motion of falling bodies, he showed that he was acquainted with the two first laws of motion, and likewise made a happy application of them. The law of reaction was a discovery of still later times. Des Cartes attempted to find out the law that obtains in the mutual collision of bodies, but failed, notwithstanding the acuteness of his genius. At last the Royal Society of London, after making it the subject of discussion at several of their meetings, devolved the task on three of their members, highly distinguished in that society, and throughout Europe, for their skill in geometry and mechanics. These were Wren, Wallis, and Huygens. The result was, that each separately made the happy discovery about the same time, in the year 1661. These three laws are the general principles on which hinges the whole of dynamical science, and indeed the whole science, whether of equilibrium or of motion.

Dynamics has continued to improve, by the happy examples that have been given of the application of these principles to the solution of particular problems: by deductions from these of other principles, less general, but more convenient for particular classes of questions; and likewise by every discovery in abstract mathematics, that great instrument for penetrating the secrets of nature. In all these respects, the contributions of Newton to dynamical science are beyond all praise. D'Alembert furnished a powerful principle, which will be given under Mechanics; and our countraman Mc Laurin, in his Fluxions, was the first to represent the motion of a body, by resolving the force that actuates it into directions parallel to fixed axis; a method that has contributed not a little to the solution of dynamical problems.

SECTION I.

Nature and Measure of Forces.

1. Force defined.—Any thing that causes, or tends to cause motion, is called force. The term is in familiar use; and the meaning attached to it by philosophers and the vulgar is the same. It is divided into two kinds, impulse and pressure. The former produces its whole effect almost instantaneously; the latter continues to act during a sensible portion of time. It comprehends pressures, properly so called, and also attractions and repulsions.

2. Measure of Weight.—We naturally judge two weights to be equal, when they produce exactly the same effect in the same circumstances; as when they counterpoise one another at the extremities of a balance, whose arms are precisely alike, or to whichever arm they are respectively suspended. We also naturally consider the parts of a body which are alike in every other respect as alike in point of weight, and thus conclude the weight of such a body to be proportional to its bulk. We actually find it to be so. Hence, by assuming the weight of a certain bulk of a certain body, a cubic foot of water for example, as an unit, and taking multiples and submultiples of that bulk, we obtain convenient measures of all weights whatsoever.

3. Measure of any other Pressure.—The pressure of gravity being thus easily measured, and also being one with which we are familiar, is well fitted to form a standard for measuring all other pressures. It is proper to bear in mind, that the specific gravity of a body is the weight of a certain bulk of it, and hence \( p = \frac{W}{RS} \).

4. Mass or Quantity of Matter measured.—Any thing is best measured by some quality which is measurable, which distinguishes it from every thing else, and which always belongs to it in the same degree, or whose variation, if there be any, is known. Weight possesses some of these properties, but in others it seems to be
DYNAMICS.

Nature and Measure of Forces.

But proof which pressure V a for not Bldi/ and different hence whether Impulse often effect the An will it has, compared...tion. — It is true, then, as it has often been said, that a force of impulse, however small, is infinitely greater than any force of pressure however great. The true state of the matter is this: An impulse produces, in a portion of time smaller than we can measure, a velocity as great as any force of pressure with which we are acquainted can produce in a considerable time.

Hence the one must be vastly greater than the other when the masses are the same; it follows, too, that we can in no case state the ratio; but it follows, at the same time, that the two forces may in some cases be equal, in consequence either of the mass moved by the force of pressure being exceedingly large, or that moved by the force of impulse being exceedingly small. Since, however, we are always acquainted with the time during which the action of impulse continues, we can in no case state the ratio of the two forces, and we can only in any case infer their equality from their balancing one another in like circumstances.

7. One Impulse compared with another.—Though we cannot compare an impulse with a pressure by the quantity of motion generated, yet we may by that principle compare impulses with one another; for the time in which each produces its effect being exceedingly small, and to us unknown, may be considered as the same; and hence the force may naturally be regarded as proportional to the momentum generated, or J = mv.

8. Force of a Body in Motion.—As we estimate a force by the quantity of motion which it communicates, so will we naturally estimate the force of a body in motion by the quantity of motion which it is capable of communicating by impulse before it is brought to rest.

Now, it will appear afterwards from the third law of motion, that a body communicates by collision just as much motion as it loses; hence it will be capable of communicating before it is brought to rest just all the motion it has, and hence its force will naturally be estimated by its momentum or quantity of motion, or J = mv. Some effects which a body is capable of producing before it is brought to rest, being proportional to mv, have made some philosophers consider the force as following that ratio. But the quantity of motion the body can communicate, seems to be the most natural measure which we can assume, as it preserves a harmony between this and other forces. The subject, however, is now generally allowed to be entirely a matter of definition; if the measure we mean to employ is explained before we set out, and strictly adhered to in the course of the investigation, it cannot alter the nature of our deductions; and the heat with which the controversy was long carried on betwixt the most eminent men, is a proof that sound metaphysics is not always found in conjunction with profound skill in mathematical and physical science. With regard to the force which a body in motion actually exerts in any given case of collision, it will be measured according to last article by the quantity of motion which it actually communicates to the other body. The method of predicting this will be given under Impulse. It will be there seen that it depends partly on the mass struck, but that when the two masses are the same, it is proportional to the velocity of the striking body.

SECTION II.

Laws of Motion, or General Rules according to which Forces act.

There are three general rules which a body obeys Laws of in its motion, whatever be the kind of body or the kind of force that impels it; whether it be a particle of dust driven by the wind, or a planet revolving in consequence of an original impulse through the celestial spaces.

These rules are the key that unlocks all the treasures
of mechanical philosophy: they form the guide, which, assisted by the torch of geometry, conducted the great Newton through all the labyrinths of nature.

Their simplicity, and the smallness of their number, give to mechanical science a generality and beauty which no other can boast.

Since they act so important a part through the whole of natural philosophy, it must be of the greatest consequence to establish their truth.

The first law describes what will happen to a body if left to itself, and unfolds a property of matter commonly known by the name of inertia. This law may therefore be called the Law of Inertia.

The second law describes what will happen when the body, impelled by any force, is at the same time acted on by several other forces, or has been previously put in motion, and therefore may be called the Law of Several Forces.

The third law maintains that when one body acts on another, the other reacts in a particular manner on the first, and may therefore be called the Law of Reaction.

**First Law, or Law of Inertia.**

A body does not change its state either of rest or of motion, unless in consequence of some external cause.

The most general principle in philosophical reasoning, indeed the foundation of all philosophy, is, that in the same circumstances the same event always happens; that, in like circumstances, a like event happens; and that the like the circumstances, the like is the event.

This principle is agreeable to the constitution of our minds, and confirmed by universal experience. In order, therefore, to shew, that in two given cases the effects shall be alike, we have only to shew that the circumstances, at least the influencing circumstances, are alike. Probably all the circumstances are never alike, and what are the influencing circumstances can only be known from previous experience on the subject in question. Again, in geometry, that property of a figure which we assume for its definition, involves all the other properties, so that they are deducible from it by a process of reasoning. This arises from the simplicity of the subject, and from the circumstance that all the other properties are of one kind. The case is different with an object existing in nature. We employ for its definition such a property, or assemblage of properties, as is sufficient to distinguish it from other objects. But the object may possess many properties which are independent of this, and cannot be deduced from it by reasoning. Having premised these remarks, we proceed to the proofs of the law.

Probably no body whatsoever is absolutely at rest, and every motion which we see commence, is perhaps only a change on some motion that previously existed. But every change evidently depends on mind, or on some other body. With regard to mind, it moves the body which it animates; but since it does not animate every body, it is not necessarily inherent in matter, and therefore its operation is to be considered as that of something external. With regard to other bodies, the direction of the change always depends on the direction of some other body, and the magnitude of the change on its distance; and hence we conclude, that if the action of mind and of other bodies were withheld, no change could ensue; that if the body were absolutely at rest, it would continue at rest; and if in motion, it would continue to move uniformly in a straight line. In short, we know from experience, that the circumstances on which its state of motion or rest depends, are not within itself, but wholly external. So long, then, as the external circumstances continue the same, so long, for instance, as there is no external action, its previous state of motion or rest must continue unaltered. This is a proof from reason.

We find accordingly, that, in proportion as we take care to diminish the effect of external action, the motion becomes more nearly rectilinear and uniform. A ball observes this law more nearly when rolled along the horizontal ground which supports its weight, than when projected through the air, where gravity causes a perpetual deflection, and more nearly on the ice which is smooth, than on the pavement where the friction is considerable. We conclude, that if the resistance of the air and of friction, and the action of gravity, were completely removed, the law would obtain with perfect accuracy. This is a proof more immediately from experience.

Farther, by assuming this law and reasoning from it, we arrive at conclusions which agree still more nearly with observation, because they refer to cases in which the causes of deviation have less influence. This holds remarkably with regard to the motions performed in vessels emptied of air, and likewise the celestial motions which seem to be performed in free space.

Thus the first law is proved partly by reason, partly by experience, and partly by its success, when assumed as a principle of philosophy.

It is worthy of remark, that even the first and last of the three proofs are founded also on experience, though more remotely than the second. Thus in the first proof we reason from the nature of matter, but that nature we had learned only from experience. In the last proof we assume the law, and apply it to the phenomena of nature, but the success of this assumption is ascertained only by experience. Indeed, it is evident, that all our knowledge of external nature must be from this source, either directly or indirectly through a process of reasoning. To say that this law enters into our very idea of matter, that it is a law of human thought, and that to suppose the contrary, would be to deny that matter is matter, does not alter, in the smallest degree, the foundation of the evidence; for granting that such were our idea of matter, whence did we derive it unless from experience? If philosophers chuse to set out with defining matter as a substance that possesses the property mentioned in this law, it is well; but still no application could be made of the law till we had learned from experience that such a substance existed.

Besides, it is evident, that though the resistance which matter offers to motion, or the effect it produces on any of our senses, might be sufficient to give us a general idea of matter, or to constitute its definition, yet, notwithstanding this idea, we could conceive matter to have obeyed a law very different from that under discussion. The circumstance that this law was unknown to the ancients, and is a discovery of very modern date, is a striking proof of what we have advanced. The first part of the law indeed which relates to rest, is abundantly obvious, because instances of apparent rest, at least, are continually presenting themselves. That part which relates to motion is rather contrary to first appearances, because, in consequence of retarding and deflecting causes, we never meet with an instance of motion perfectly uniform and rectilinear. But though the whole were a matter of vulgar observation, it would be proper to direct upon it a cautious and philosophical eye. If the facts on which it rests are so very obvious, their
evidence cannot surely be impaired by inquiry. First impressions often need to be corrected by subsequent reflection. Even some of the common axioms of geometry have been contested. Much more must the first principles of physical science be open to discussion. It was held as a first principle by Aristotle, that the earth is at rest merely because it appears to be so, and it required nearly two thousand years to show that this principle is false.

Second Law, or Law of Several Forces.

The effect is always proportional to the force impressed, and takes place in the direction in which the force acts; or, more precisely, provided the force exerted is the same, the effect of its momentary action is the same, whether the body was previously at rest or in motion, and whether it is acted on by that force alone, or subjected at the same time to the action of several other forces; so that the effect of the joint action of several forces is an exact compound of their separate effects, or the same as if each had acted successively. Thus the effect of two forces at once on a body in the same direction, is equal to the sum of their single or separate effects, &c.

This is a proposition which cannot be deduced either from the general definition of matter, or from the first law. We can infer, indeed, that when the body is acted on by several forces, the motion that ensues must be uniform and rectilinear; for, though urged in several directions, it can set only in one direction, and in whatever direction it sets out, it must continue to move uniformly by the first law.

This seems to be the amount of what can be proved by reasoning from the general principles. The particular direction in which the body shall set out, depends in many cases on the effect of each force; and that this effect would be the same as when the force acted alone, could be gathered only from experience. To say that this law is a mere affair of definition, and that in all cases we measure a force by the effect which it is found to have produced, whether alone or in combination, seems to be very unphilosophical. We measure a force by the effect which we find it has produced in a given case; (the more nearly the body was at rest, and the less under the influence of other forces the better;) but experience alone could inform us, that the measure deduced in this case would exactly agree with the effect of the same force in all other cases. If, indeed, the influencing circumstances in all other cases were the same; we would be justified in concluding that the effect would be the same. But how could we know unless from experience, that the circumstance of other forces acting in combination would not be an influencing circumstance?

Analogue experience could by no means have led us to the conclusion. We find that a very slight difference of circumstances is sufficient to change the mechanical action of bodies. We find that at sensible distances bodies attract, while at insensible distances they repel one another, so that a mere difference of distance, less than the millionth part of an inch, is sufficient to change the action from attraction to repulsion, that is, from one direction to another directly opposite. We find in chemistry, that two bodies, which separately burn animal matter, yet in a state of combination exert no such action. How could we know unless from experience, that in the case of forces also, the qualities of the ingredient are not in a great measure lost in those of the compound? In estimating the effect on the body, we have a difficulty in abstaining from the notion that the body has been immediately under the influence of all the forces; but we should consider that an event has intervened, that a new single action has arisen from all the separate actions, that it is only a knowledge of this action which can enable us to calculate the effect, and that this action can be learned only by experience. Many attempts have been made to demonstrate the law, but the view given above is sufficient to show that such attempts must be fruitless. The same conclusion is suggested, when we carefully analyse the most celebrated of these pretended demonstrations. The general definition of matter, and the first law, are found to be totally inadequate to conduct to the second. The mathematician, labouring under the burden of his task, finds himself, at every step, obliged to make assumptions of the same nature as the proposition to be proved. Thus lately, Dr Olynthus Gregory, in his valuable work on mechanics, (p. 16.) first assumes, that when forces act in the same direction, the result is obviously equal to the sum of the separate effects, and when in opposite directions, equal to their difference. He, indeed, wishes to give this principle the air of demonstration, by referring to the definition of force, and the third law of motion. But it has appeared already that the mere definition is quite insufficient, and, as to the third law, it is perhaps even less obvious than the second. Having made this assumption, he advances with its aid to the case of two forces acting at an angle. But he has not gone far, when he is obliged to make another assumption, viz. that "if to a material point already kept in equilibrium by a system of forces, another system is applied also in equilibrium, this will not destroy the pre-existing equilibrium." This is by no means manifest, from the general definitions of force and of body. It is a second assumption of the very same nature as the proposition to be proved. It assumes that the action of forces will not be altered by their composition with other forces. It is in fact a case of the law in question; nor is it a case either more obvious to reason, or more easily confirmed by experience, than many other cases. Other assumptions of exactly the same nature are drawn in as he advances, and yet he professes to tread in the path of the celebrated D'Alembert, and even to improve upon his demonstration, after it had been already improved by Franconur.

There is an illusion on this point, arising from our mathematical habits. In pure geometry, the length of the reasoning that conducts us to the conclusion, does not in the least impair the certainty of that conclusion, or our conviction of its truth. Each previous step being certain, the last must be certain also. We are apt to have the same opinion of physical science; but in doing so we shall often be egregiously mistaken. If the principle from which we set out is doubtful, the conclusion must be at least as doubtful, however pure our subsequent reasoning, and however free it may have been from other assumptions. But if, at a number of stages in the reasoning, we assume other doubtful principles, the conclusion must depend on the chance that all these principles are true, and is therefore probably much more doubtful than any of them; just as in throwing a die there is much less chance for an ace in each of ten successive throws, than in one throw. If we labour so much to shew that this law is indemonstrable, it is not because we undervalue the force and advan-
DYNAMICS.

289

Laws of
Motion.

The Third Law of Motion.

When one body acts on another, the other exerts an equal force against it in the opposite direction, which is usually expressed by saying, that action and reaction are equal and contrary.

This law holds whether the bodies attract or repel one another, and whether they act at a distance or in apparent contact; and the grand basis on which it rests is experience.

Thus, if one body attracts another at a distance, the other attracts it with equal force in the opposite direction; so that, if motion ensues, the quantity of motion produced in the one is equal to that produced in the other; and, if motion is prevented, the pressure necessary to prevent it in the one, is the same as in the other.

If one body repels another at a distance, the other repels it with equal force in the opposite direction, the equality of force being estimated in the same way as above.

The same law holds when the bodies act in apparent contact. In this case, if they attract, you have no greater reason to ascribe the force with which they cohere, or which is necessary to separate them, to the attraction of the one than of the other; if they repel, as in impulse or pressure, the reaction seems to be intimately connected with our first conceptions of matter. When one body strikes against another at rest, without producing motion, the same change is induced on the striking body, as if it being fixed had been struck by a body of equal mass and velocity in the opposite direction; and if it be the hand that strikes, the same sensation is experienced. These circumstances imply an equal reaction. If two bodies meet when moving in opposite directions, with equal momenta or quantities of motion, we may presume they will stop one another; for, equal momenta being the effects of equal forces, may be supposed to possess equal forces, and such will balance one another. This is actually the case. It appears from this that a force will be able to destroy just as much motion as it can communicate, and hence that it may be measured by either of these effects. If a body strike another at rest, or moving before it in the same direction, we may expect from the analogy of the last case, that the reaction will be equal to the action. We accordingly find that the quantity of motion which the impinging body has communicated is equal to what it has lost, that is to what the other by its reaction has destroyed. If the bodies move in opposite directions, we may presume that the body with the greater momentum will prevail, that it will first spend some of its motion in reducing the other to rest, and then some of the remainder in moving the other, and that in both parts of the process the reaction will be equal to the action, according to the two foregoing cases. This is also really the case. The same holds in all analogous cases, when bodies press against one another. If the bodies, in consequence of meeting, alter their shape, and again recover it, they will act on one another during the recovery, and then also the action is mutual and equal.

The same law may be expected to hold, and actually holds, when one body acts on another through the medium of a third, as when one body pulls another by means of a thread, or repels it by means of a pole. In this case the third body is merely a medium of communication, and cannot be supposed to alter the action of the forces, unless that its mass when considerable would need to be taken into the account.

SECTION III.

Composition of Forces.

A body is often acted on by several forces at once, and it is required to find the effect of this joint action, or a single force which would produce the same effect. This single force is called the equivalent, resulting, or compound force; and the process for finding it is called the composition of forces. The whole depends on the second law of motion.

CASE I. Two forces applied at the same point of a body.

—If they act in the same direction, the equivalent will be in that direction, and equal to their sum; if in opposite directions, the equivalent will be in the direction of the greater, and equal to this difference; if at an angle, the equivalent will be in the same plane, and represented by the diagonal of a parallelogram of which the two sides represent the simple forces.

This follows immediately from the second law of motion; the only case which needs any demonstration is that when the forces act at an angle.

If the one force alone would make the body move along AB, and the other along AC in the same time, CCXL. the two by their joint action will make it move along the diagonal AD in the same time.

For by the second law, its motion parallel to AB will be equal to AB, and its motion parallel to AC will be equal to AC; hence at the end of the time it must be at D. In like manner, suppose that by the separate action of the forces, the body would at any intermediate point of time be at E and F, then completing the parallelogram FE, their joint action will bring it to G at that time. But it is easy to see that AB : AE : : AC : AF. For both motions being uniform, first law of motion, the spaces past over in both cases are proportional to the times, and hence proportional to one another. Hence the two parallelograms are similar, and consequently about the same diagonal. (Enc. xxxvi. G.)

If the forces are pressures, the effects of the momentary action will be extremely small, but the same demonstration still applies. Though equilibrium is not
The direct object of this article, yet the following remarks may not be improper, as tending to illustrate the subject. If no motion ensues, still the diagonal will express the tendency to move, as well as the direction of that tendency. It will express the force applied in the contrary direction, which has destroyed the motion, whether that force be an active one, or merely the reaction of a fixed obstacle. In the case of pressures, it will express the pressure that arises against the obstacle; a conclusion which we are justified in drawing from the analogy established in the first Section between pressures and the motions which they generate, and which, besides, is confirmed by experience. The case of impulses is illustrated in some treatises of natural philosophy, by a complex piece of machinery. The case of pressures may be illustrated by the following simple apparatus.

Let the three weights hang around the two fixed pulleys, as in the Figure, be in a state of equilibrium; let AB, AC, be taken proportional to the weights N, M, respectively, which act in the directions of AB, AC; then the parallelogram being constructed, the diagonal AD, which is the equivalent according to our proposition, will be found to be vertical, that is directly opposite to P, and also proportional to P.

Con. 1. The equivalent is represented by the third side of a triangle, whose other two sides are drawn in succession parallel and equal to the single forces. This is evident by inspecting the triangle ABD. It is evident also, that the included angle of this triangle is the supplement of that at which the forces act.

The sides of any triangle perpendicular respectively to those of ABD, will also express the magnitudes of the forces, and of their equivalent; for such a triangle will be similar to ABD.

Con. 2. Given two forces and the angle which their directions make, the equivalent may be found either by constructing the parallelogram, or the triangle, or by trigonometrical calculation. The angle BAD being found, will express the direction of the equivalent.

It is easy to show by help of Eucl. 12, 13. 2. that if $a, b$ denote the two forces, $c$ the angle which they make, and $d$ their equivalent,

Then $d = \sqrt{a^2 + 2ab \cos c + b^2}$, the radius being unity; also the sine of the angle which $d$ makes with $a$ is $\frac{a \times \sin c}{d}$.

It is easy to see from 47. 1 Eucl. that if the angle is right, then $d = \sqrt{a^2 + b^2}$.

Con. 3. When the two forces act at an angle, the equivalent is less than the sum, and greater than the difference; and it is more nearly equal to the sum the smaller the angle, so that when the angle vanishes it will become equal to the sum.

This is evident from the properties of a triangle.

Con. 4. The simple forces are inversely as the perpendiculars dropped on their directions from any point in the direction of the equivalent.

1st. If dropped from D, the $\triangle ACD = \triangle ADB$, hence $AC \times DM = AB \times DN$. Therefore $AC : AB : : DM : DN$.

2d. If dropped from any other point G, it is easy to see by similar triangles, that $DN : DM : GE : GF$; hence $AC : AB : : GE : GF$.

Case 2. Any number of forces applied at a point.——The equivalent will be found by compounding two according to last case, then compounding the equivalent with a third, and so on.

If all the forces lie in one plane, it is evident that the most expeditious way of finding the equivalent will be by drawing successively lines equal and parallel to those representing the forces, as in Figure; and then the line drawn in completing the polygon will be the equivalent.

The equivalent of three forces is the diagonal of a parallelopid, of which the three forces are the adjacent lineal edges.

$AB, AC, AD$ being the three forces applied at A, the diagonal AE will be the equivalent.

For joining BE, AG, the equivalent of $AC, AD$ is $AG$, because $AC, AD$ is a parallelogram, and since the plane in which the parallels $AB, EG$ are, is cut by parallel planes, the lines of common section $BE, AG$, will be parallel, (Eucl. 16. 11.) hence the Figure BG is a parallelogram, therefore $AE$ is the equivalent of $AB, AG$, that is of $AB, AC, AD$.

It is easy from the Figure to perceive, by help of (Eucl. 47. 1.) that if the parallelopid is rectangular, and if $a, b, c$ denote the three simple forces, and $d$ the equivalent, then $d = \sqrt{a^2 + b^2 + c^2}$.

Case 3. Two parallel forces applied to different points of a body in the same direction.——Since the two parallels may be considered as coming from a point infinitely distant, or as making an infinitely small angle with one another, their equivalent will be equal and parallel to their sum by Cor. 3. to Case 1, and it will divide the straight line joining the points of application in the inverse ratio of the forces.

For by Cor 4, the forces are inversely as the perpendiculars on their directions, which, in this case, are as the segments of the joining line. The Figure is sufficient to show this.

Case 4. Two parallel forces applied in opposite directions.——The equivalent will be equal to their difference, in the direction of the greater, on the other side of it, and divide the straight line produced through the points of application in the inverse ratio of the forces.

This will follow from last case; for let NA be a force which, together with CD, balances FE, or, in other words, which prevents the line AD from moving, then, by last case, $NA + CD$ must be $= FE$, and CD being to NA, $AE : ED$, CD will be to FE, as $AE : AD$; but since NA keeps the line from moving, it must be equal and opposite to the equivalent which we are seeking; hence, if $AG = AN$, what we have demonstrated of AN will hold of AG.

Case 5. Any number of parallel forces.——Compound two, then the equivalent with a third, and so on. If some act in one direction, and others in the opposite, it will be most convenient first to compound all those in one direction, and then all those in the opposite; and, lastly, compound the two equivalents. It is easy to see from the nature of the process, that the point through which the last equivalent must pass will be the same, so long as the forces and points of application are the same, although the direction of the forces should be changed. This remarkable point is called the centre of parallel forces.

Case 6. Forces applied to different points, but not parallel.——If they are in one plane, you may produce them till they intersect, and then compound them two and two. If they are not in one plane, but converge toward one point, you may consider them all as applied at that point, and then find their equivalent, as in Case 2. If they do not converge toward the same point, the case requires the reduction of forces, and will be explained under Art. 4. of next Section.
SECTION IV.

Resolution of Forces.

This consists in resolving a single force into others to which it is equivalent, and which are to have given directions.

1. If the given directions are all in the same plane with that of the given force, we can always perform the resolution into any number of forces, by inverting the process of Case 1, last Section.

Thus, if two, we will make a parallelogram, of which the diagonal represents the given force, and the sides are parallel to the given directions. If three, we may first resolve a part of the given force into two of the given directions, and then the remainder into one of these directions, and the third direction.

2. When the given directions are not in the same plane with that of the given force, we cannot resolve it into two, but we can always resolve it into three given directions, provided two of them are in one plane. We can first resolve it into two forces, one of which is parallel to one of the given directions, and the other parallel to the plane of the other two; and then resolve this other into the other two given directions.

3. One important application of the resolution of forces, is to find the effect of a force in a given direction, or in other words, to reduce it to a given direction.

It is evident that, in order to do this, we have only to resolve the force into two, one of which is parallel to the given direction, and the other at right angles to it. The latter can have no effect in the given direction, and therefore the other will express the whole effect.

4. Another important application of this subject is to the composition of forces.

The last case of composition cannot be managed unless by resolution. You may fix on three directions, two of them in one plane; resolve each force into three, parallel to these directions, find the equivalent of all those parallel to one line, then of those parallel to another, &c. then compound the three equivalents, if they pass through the same point; if not, the problem is impossible, that is, there is no single force equivalent to them all.

The most convenient directions to fix on will be three straight lines passing through the same point at right angles to one another, and the most convenient way of resolving, will be to calculate on the principle mentioned in Case 2d of last Section, that the three adjacent edges of a parallelopiped compose a force equal to the diagonal. Hence, since in this case the parallelopiped is rectangular, let $\mathbf{F}$ denote any force.

Then $R \cdot \cos \alpha \cdot f \cdot \frac{1}{\sin \alpha} = \text{the force estimated in that direction.}$

Let $b, c, d, e$ denote the three equivalents found; then, if they pass through the same point, they will be three edges of a rectangular parallelopiped, of which the diagonal is the equivalent sought, which call $m$; then $m = \sqrt{a^2 + b^2 + c^2}$. The same method may be applied with advantage to Case 2d of composition, when the forces are not all in one plane; and even when the forces are all in one plane, a similar method will sometimes be convenient, only in that case it will be sufficient to resolve each force in the direction of two perpendicular lines. It is evident that in Case 2d the composition can always be effected, because the three equivalents will always pass through the point to which all the given forces are supposed to be applied.

SECTION V.

Application of the General Principles of Dynamics to some Cases in which the bulk of the Body is overlooked, or rather in which the Body is regarded as having its whole Matter collected in a Point.

CASE 1. A body acted on by an impulsive force.—By the first law, the motion will be uniform and rectilinear.

Hence, if $v$ = the velocity, or space through which the force will make the body go in a certain unit of time, $t = \text{the whole time or number of units during which the body moves}, s = \text{the whole space or line passed over},$ it is evident that

$$s = vt.$$

This is the fundamental equation, which involves all the rest.

Thus $\frac{s}{v} = t$.

Hence also $s = \frac{1}{v}$ when $s$ = the same, and $s = \frac{1}{v}$ when $t$ = the same.

$\frac{s}{v} = t$ when $s = \frac{1}{v}$ when $t$ = the same, and $s = \frac{1}{v}$ when $t$ = the same.

CASE 2. A body acted on by two impulsive forces.—If they act in the same direction, the velocity will be equal to the sum of the separate velocities.

If in opposite directions, it will be equal to their difference.

If at an angle, the velocity and direction will be found by the rule given for finding the equivalent of two forces, in last Section; that is, by finding the diagonal of a parallelogram, of which the sides represent the separate velocities.

CASE 3. A body acted on by an equal impulsive force at equal intervals of time in the same direction.—Suppose the force is such, that during the first interval of time the body will pass over the space $a$.

With this velocity it would go on uniformly, but at the end of the interval it receives an equal impulse, which, according to the 2d law, will just add as much to its velocity, and so on; hence during the second interval, it will pass over the space $2a$; during the third, $3a$, &c.; so that if $t$ denote the whole time, or whole number of intervals, it will, during the $t^{th}$ interval, pass over the space $ta$.

Hence it is evident, that the velocity at any period of the motion will be in proportion to the number of intervals, or to the time that has elapsed.

The whole space will be $= \text{the sum of the arithmetic progression } a, 2a, 3a \ldots \begin{cases} \frac{a}{2} + \frac{a}{2} = a \times \frac{t + 1}{2} \end{cases}$.
Con. 1. If \( t \) the number of intervals is very great, then \( \frac{a}{t} \) will be very great in comparison with \( t \), so that the space will be \( \frac{a t^2}{2} \) nearly.

Con. 2. Hence, too, in this case, the space will be nearly proportional to \( t^3 \), since \( a \) and \( t \) are constant.

Con. 3. The space over which the body would go with the last acquired velocity in the time \( t \) would be \( t a \cdot t = t^2 a \), nearly double the space already gone over, if \( t \) is great.

Case 4. A body acted on by pressure, always acting in the same direction, and with the same intensity.

When once a body has acquired a finite velocity, by the action of an unremittting force, and the action has ceased, the motion (according to law 1st.) will be perfectly uniform, and therefore all its circumstances calculated as in Case 1. But in the present case, a considerable time elapses before a considerable velocity is acquired, and it is interesting to investigate the circumstances of the motion during the lapse of that time.

The action being renewed at the end of every instant, the velocity will not remain the same longer than an instant, or the motion will be perpetually accelerated.

The velocity at any point is expressed by the space passed over during the next instant, or by the space it would pass over during the next unit of any magnitude, were it to preserve its motion unaltered, or nearly by the space actually passed over during the next moment.

When the force is supposed to act with the same intensity, the velocity added at the end of each instant will be the same; and hence if \( t \) denote the number of instants in any finite portion of time, and \( v \) the velocity acquired, it follows by the demonstration in last case, that \( v = \frac{1}{t} \). Also, since in this case \( t \) is infinitely great, \( s = \frac{t^2}{2} \) exactly.

but \( v = \frac{1}{t} \); hence \( s = \frac{v}{t} \).

For the same reason, in this case, the space through which the body will go with the last acquired velocity in the time \( t \), will be exactly twice the space it has already gone over.

Con. 1. In the case of any pressure, having ascertained by experiment the space passed over in a certain time, such as a second, we will have the space that would be passed over during the next unit with the motion unaltered, that is, the velocity acquired, and we will be able, given any one of three \( t, v, s \), to find the other two.

Thus we will be able to find \( s \) when \( t \) is given, or \( t \) when \( s \) is given, by the formula \( s = \frac{t^2}{2} \).

We will find \( v \) when \( t \) is given, or \( t \) when \( v \) is given, by the formula \( v = \frac{1}{t} \).

And we will find \( s \) when \( v \) is given, or \( v \) when \( s \) is given, by the formula \( s = \frac{v^2}{2} \).

Or an absolute equation may be derived, for each of the six problems that may arise. Thus, let \( p \) be the space passed over during the first unit of time, and consequently \( 2p \) will be the velocity acquired during that time.

Then \( 1 : p : : p : s = p \cdot t^2 \).

Hence \( \sqrt{\frac{s}{p}} = t \).

\[ 1 : t : 2 p : v = 2 p t \]

Hence \( \frac{v}{2p} = t \).

\[ 4p^2 : v^2 : : p : s = \frac{v^3}{4p} \]

Hence \( 2 \sqrt{\frac{p}{s}} = v \).

Con. 2. \( s = \frac{v}{t} \), and consequently \( \frac{s}{p} = \frac{t}{t} \), and \( \frac{v}{v} = v \).

Con. 3. If the times, counting from the beginning of the motion, are taken as 1, 2, 3, \&c. the spaces will be as 1, 4, 9, 16, \&c. and the spaces passed over during the successive equal intervals of time, will be as the differences of these numbers, that is, as the odd numbers 1, 5, 7, \&c.

Con. 4. Since with the same pressure, the velocity acquired is proportional to the time, in comparing two pressures, we will obtain the same ratio, whatever be the time we assume. This shews the consistency and propriety of the measure we adopted.

Con. 5. If one of the two pressures produce the same velocity in the same body in half the time, it is evident it would, in the same time, produce double the velocity; hence the force would be double, and so on. Therefore, when the mass and the velocity, or \( m \) and \( v \) are the same, then \( f = \frac{1}{t} \). Hence we have \( f = \frac{m v}{t} \), or \( f = \frac{m v}{t} \), if we measure \( f \) by the effect in an unit of time.

Con. 6. Again, since \( v = \frac{2s}{t} \), if we substitute the latter in the expression of the foregoing corollary, we get \( f = \frac{2m s}{t} \).

Con. 7. Also, since \( t = \frac{2s}{v} \), if we substitute the latter, we get \( f = \frac{m v^2}{2s} \).

Con. 8. Further, it may sometimes happen, that we do not know the circumstances of a motion from its commencement, and we may wish to determine the force by observing the increments on the time, space, or velocity.

Now, it is easy to shew that the above formula will apply to the increments, reckoning from any point, as well as from the beginning.

Thus, let \( v, t, s \), denote the corresponding increments on \( v, t, s \).

Since \( v = \frac{t}{t} \), hence \( \frac{v}{t} = \frac{v'}{t'} \).

Therefore \( f = \frac{m v'}{t'} \).

Since \( s = \frac{t^2}{2} \), hence \( s = \frac{s'}{t'} \).

Therefore \( f = \frac{2m s'}{t'} \).

Since \( v = \frac{s}{t} \), hence \( \frac{v}{t} = \frac{v'}{t'} \).

Therefore \( f = \frac{m v'}{2s'} \).

Con. 9. When the mass remains the same, the force will be measured by the velocity generated in the unit of time; and the expression for it will evidently be had by dividing the above formula by \( m \), or by expounding it.

Con. 10. If the force continually increases, the velocity will increase faster than in the ratio of the times, and the spaces faster than in the ratio of the squares of the times. The reverse will hold, if the force continually diminish.

Case 5. A body acted on by pressure, always in the same direction, and continually varying its intensity according to a certain law. Here, as in last case, the motion being uniform only for an instant, it will follow by
In a similar manner, since by last case \( f = \frac{(v^2)}{2s} \), it follows that in this case \( f = \frac{2v^2}{2s} = \frac{v^2}{s} \).

Also since by last case \( f = \frac{2s}{v^2} \), hence in this case \( f = \frac{2s}{v^2} \).

Farther, since \( i = vi' \), and consequently \( v = \frac{i}{t} \), therefore taking the fluxions of these quantities \( v = \frac{s}{i} \), substituting this instead of \( v \) in the second formula, we get \( f = \frac{s}{i} \), which becomes \( f = \frac{s}{i} \) when \( i \) constant.

Hence, bringing together all the formulæ necessary in the present case, we have

1. \( s = s' \), hence \( \frac{s}{s} = i \), and \( \frac{s}{i} = v \)
2. \( f = v \), hence \( f = t \)
3. \( f = \frac{v^2}{s} \), hence \( f = \frac{v^2}{s} \).
4. \( f = \frac{s}{i} \), hence \( f = \frac{s}{i} \).
5. \( f = \frac{s}{i} \), which becomes \( f = \frac{s}{t} \) when \( i \) constant.

These formulæ may be employed either for finding the relations of \( s, v, \) and \( t \), when you know the law of the force, expressed according to some function of one of them; and, conversely, you have only to substitute the given relation in the proper formula, and then integrate. The law of the force is commonly expressed according to some function of \( S \); the two following problems will involve almost every thing that can be desired on this subject.

**PROB. I.**

Suppose that the force varies as some given power of the distance from a point toward which the body is moving, and which we may call the point of attraction, it is required to determine the relations of the space passed over, the time elapsed, and the velocity acquired, so as to enable us to infer one from another.

Let \( s \) = the distance of the body from the point of attraction at the outset, 
\( s' \) = the space it has past over, 
\( v \) = the velocity acquired, 
\( t \) = the time elapsed, 

then \( a - s \) will be the distance now from the point of attraction, and \( a - s \) multiplied by some constant quantity, which we may call \( m \), will be the force that now acts on the body. It is evident that in any case \( m \) will be known when we know the force at some given distance.

To discover the relations of \( v \) and \( s \), we will substitute the expression for the force, in the third formula, where \( v \) and \( s \) occur.

Hence \( m \times (a - s)^{n+1} + C = v^2 \).

Now the constant quantity \( C \) must be such that \( v = 0 \) when \( s = 0 \), hence \( C = \frac{m(a^{n+1})}{1} \).

Hence \( m \times (a - s)^{n+1} - ma^{n+1} = v^2 \).

This applies whether \( n \) be positive or negative, whole or fractional, unless when \( n = -1 \). In this case, the formula is evidently absurd, and in order to have the proper fluents, we must recur to the fluotion equation, which becomes \( m \times (a - s)^{n+1} \times s = v^2 \).

Hence, taking the fluents, and employing \( L \) to denote hyperbolic logarithm, we get \(-m \times L (a - s) + C = \frac{v^2}{2} \).

The constant quantity \( C \) must be such that \( v = 0 \) when \( s = 0 \), hence \( C = m \times L, a \).

Consequently \( m \times (L, a - L_1, (a - s)) = \frac{v^2}{2} \).

Thus, \( m \times (L, a - L_1, (a - s)) = \frac{v^2}{2} \).

Again, to discover the relations of \( s \) and \( t \) in any case, we have only by the above formulæ to find the expression for \( v \) in terms of \( s \), and substitute that expression instead of \( v \) in the fundamental equation \( \frac{s}{v} = t \). We will thus have a fluxional equation involving the fluotions of \( s \) and \( t \) with known terms, and taking the fluents, we will obtain an equation involving \( s \) and \( t \) themselves with known terms.

Thus, \( n = -2 \), which is one of the most interesting cases, then

\[ v = \sqrt{2m \times (a - s)^{a^2} - s^2} \]

Hence \( t = \frac{s}{\sqrt{2m \times (a - s)^{a^2} - s^2}} \), on multiplying each term of the last fraction by \( a - s \).

Hence \( t = \frac{s}{\sqrt{2m \times (a - s)^{a^2} - s^2} \times a} \times \frac{a - s}{a - s} \times s \).

Now the last part of this expression, viz. \( \frac{a - s}{\sqrt{a - s^2} \times s} \), is evidently equal to \( \frac{a - s}{\sqrt{a - s^2} \times s} + \frac{a - s}{\sqrt{a - s^2} \times s} \), the first term of which has for its fluent \( \sqrt{a - s^2} \), and that
Dynamics.

Application of the second (by supposing \( s = \frac{a}{2} - z \)) will be \( \frac{a}{2} \times \text{an} \) arch whose cosine is \( \frac{2z}{a} - \frac{a}{2} \).

Hence \( t = \sqrt{\frac{a}{2m} \times \left\{ \sqrt{a^2 - s^2} + \frac{a}{2} \times \text{arch} \right\}} \) and this case requires no correction, because \( s \) must be \( 0 \) when \( t = 0 \).

Con. 1. When \( s = a \), then \( v \) is infinite, and \( t = \sqrt{\frac{a}{2m} \times \frac{ac}{2}} \) where \( c \) is the circumference of a circle whose diameter is unity; hence the whole time of descent to the centre of attraction by a body setting out at different distances is \( \frac{a}{2} \sqrt{a^2 - a} \), that is proportional to the square root of the cube of the distance.

If the force varies as some given power \( n \) of the distance from a given point farther back, than that from which the body sets out, the equation that expresses the relation of \( v \) and \( s \) will be the same as before, only having \( n+1 \) instead of \( n \).

Con. 2. Hence, if the body is acted on by several pressures in the same or opposite directions, the effect may be found by calculating the separate effects, and then taking the sum or difference.

Problem II. Suppose that the relation between \( t \) and \( s \) is given; suppose, for instance, that \( t = \frac{a}{a-s} \), and consequently \( s = m \times a \times a \times d^3 \), \( m \) being a known quantity, required the law of the force expressed according to \( t \).

Since \( f = \left( \frac{s}{i} \right) \)

if we regard \( s \) as constant, we get \( f = \frac{s}{t^3} \).

Now \( t = \frac{m \times (a-s)^n}{d^3} = \frac{n m \times (a-s)^n}{d^3} \),

hence \( t^3 = \frac{n^3 m^3}{d^3} \times (a-s)^{3n} \).

and \( f = \frac{n m s^3 \times (n-1) \times (a-s)^{n-2} \times -s = \frac{n m s^3 \times (n-1) \times (a-s)^{n-2}}{n^2 m^2} \).

hence \( f = \frac{n m s^3 \times (n-1) \times (a-s)^{n-2}}{n^2 m^2} \).

Here \( f = (a-s)^{1-n} \).

The great object in this case of dynamics is, given the relation of the force to \( s, v, \) or \( t \), to find the relation of these to one another, or, given the relations of two of these to find the relation of the force to them. The relation most easy to observe, is that of the force to \( s, \) or of \( s^2 \) to \( t \).

Case 6. A body acted on by impulse and pressure at the same time.—It is necessary to bear in mind, that the impulse ceases to act almost immediately, but that the pressure continues to operate. It is evident that the effect will be the same, as if the body had acquired a finite velocity in any other manner, and then begun to be acted on by the pressure.

Variety 1. When the impulse and pressure both act in the same direction.—It is clear that the motion will be in that direction, and that the effect in any given time will be found, by calculating separately the effects of the impulse and pressure, and adding them together.

Variety 2. When the two forces act in opposite directions.—It is evident, that the motion will be continually retarded, and at last destroyed. To find the relations of \( s, v, \) and \( t \), you have only to calculate the effect of the initial velocity, supposing it to remain the same, and then subtract the effect of the pressure. To find the time in which the whole initial velocity will be destroyed, or the body brought to rest, we have only to calculate in what time the pressure would be able to generate that velocity. It is evident, that if the pressure acts always with the same intensity, the motion will be uniformly retarded, or the body will lose equal portions of velocity in equal times; also, the whole time will be proportional to the initial velocity, and the whole space proportional to the square of the whole time, or of the initial velocity. Thus, it is evident, this variety of Case 6th will come within the range of former problems.

Variety 3. When the impulse and pressure act at an angle.—This is by far the most important and most difficult variety, and is usually discussed under the title of Central Forces.

If a body, already proceeding with a finite velocity, in consequence of an impulse, or some other cause, is acted on at finite intervals of time by new impulses, each of which differs in its direction from that of the previous motion, its path will evidently be a succession of straight lines making angles with one another. If, instead of being an impulse, the force be pressure, and act incessantly, the straight lines will become infinitely short, and the path consequently become curvilinear. The curve will lie wholly in one plane, if the direction of the pressure be always in the same plane with the original direction of the motion, and it will be concave on that side toward which the pressure is directed. Again, since a body, if left to itself, moves in a straight line, we may conclude, when it moves in a curve, without being compelled to it by a fixed obstacle, that there is a force of pressure constantly deflecting it from the direction of the tangent.

The arch, through which the body moves in an instant, or through which it would move in any unit of time in the direction of the tangent, if the pressure were to cease, is the projectile velocity at that point of the curve.

In the cases that most commonly occur, the pressure is an attraction; it is commonly directed to the same point during a considerable part of the motion; that point is called the centre of attraction, and the force is called a centripetal force.

The force with which the body, in consequence of its projectile motion, endeavours to recede from the centre of attraction, is called a centrifugal force. These two forces have the general name of central forces.

A straight line, drawn from any point of the curve to the centre of attraction, is called the radius vector.

The angular velocity at any point of the curve, is the velocity with which the radius vector at that point describes an angle, that is, the angle which it passes over in an instant, or that which it would pass over in any unit of time, were its angular motion to remain uniform.

When the line which the body describes returns into itself, like a circle or an oval, it is called an orbit, and...
DYNAMICS.

Application. the time of describing the whole of it is called the periodic time.

The following are the most important propositions on the subject of central forces.

Prop. I.
If the centre of attraction remains always the same, the curve will lie wholly in one plane, passing through that centre; and the areas described by the radius vector, will be proportional to the times of description.

First, suppose the central force to act during equal finite intervals of time; suppose $c$ the centre of attraction, $AB$ the line passed over in one of the equal intervals, the body with its uniform motion would, during the next equal portion of time, go over a line $BD=AB$, but at $B$ it is acted on by the central force. Suppose the momentary action is such, that in the same time the body would move along $BE$, then completing the parallelogram, $BF$ will be the real line of the motion. Joining $CD$, the $\Delta ABC$ is $\approx \Delta BDC$, because they have equal bases, and the same altitude; and the $\Delta FBC$ is $\approx \Delta BDC$, because they are on the same base, and between the same parallels; therefore, $ABC=FBC$. The same thing may be shewn with regard to the next triangle, &c. Hence, the sum of all the triangles, or the whole area, described in a given time, will be proportional to the time of description. Also, all the triangles are in one plane; for $CFH$ is in the plane of $CDB$, since they are between two parallels which necessarily lie in one plane, and $CDB$ is evidently in the plane of $ABC$; therefore $CFB$ is in the plane of $ABC$. It is clear, also, that the point $C$ must always be in the plane of the Figure. Suppose now that the central force acts incessantly, or that the equal intervals of time are infinitely small, the path then becomes a curve, and the triangles become infinitely small, but still the same demonstration will hold; and hence we infer the proposition.

Conversely.—Prop. II.
If the curve described lie wholly in one plane, and the radius vector drawn from a certain point in the plane, always describe areas proportional to the times, that point is the centre of attraction.

For around any other point than the centre of attraction, the areas described in equal times cannot be equal.

Thus, in the same Figure, take any other point $G$; it is evident that $GBF$ cannot be equal to $GBA$; for in order that this might hold, $DF$ would need to be parallel to $GB$, whereas it is parallel to $CB$.

Prop. III.
The projectile velocity at any point of the curve is inversely as the perpendicular let fall on the tangent at that point from the centre of attraction.

For the small triangle described in an instant, by the radius vector being everywhere of the same area, its base must be inversely as its perpendicular; but the base is the projectile velocity, and the perpendicular on the base is just the perpendicular on the tangent.

Prop. IV.
The angular velocity is inversely as the square of the distance or of the radius vector.

Let $ACB$ be the small triangle described in an instant, and therefore the angle $C$ the angular velocity.

From the nature of the circle, the angle $C$ is $= \frac{AD}{AC}$; but the area of the triangle described in an instant being always the same, the perpendicular will be inversely as the base; hence, $AD = \frac{1}{AC}$, because $AC$ is ultimately $= CB$; hence the angle $C = \frac{1}{AC^2}$; or let $a$ be the angular velocity, and $r$ the radius vector, then $a = \frac{1}{r^2}$.

Prop. V.
The centripetal force, at any point, will be proportional to the versed sine of the arch described in an instant, reckoning the versed sine toward the centre of attraction.

For the small arch $AD$ may be considered as the diagonal of the parallelogram $EB$, of which the side $AB$ expresses the effect of the projectile force, and $AE$ that of the central force.

Cor. 1. You may measure the centripetal force by the velocity generated in an instant, and then you will employ twice $AE$; but the ratio is of course the same. Cor. 2. $BD$, which is equal to $AE$, is the instantaneous deflection from the tangent, and may also serve to measure the centripetal force.

Circle.—Prop. VI.
Sectors of a circle being proportional to the arches on which they stand, when the body describes the circumference uniformly, the radius vector will describe the area uniformly; hence the centre of the circle must be the centre of attraction by Prop. 1. The converse follows in a similar manner from Prop. 2.

Prop. VII.
If the body describe a circle, the centripetal force at any point is directly as the square of the projectile velocity, and inversely as that part of the radius vector produced which the circle intercepts, often called the deflective chord.

Let $AB$ be the arch described in an instant, $BD$ $\parallel$ the tangent, $BD$ the tangent, $C$ the point of attraction, then $AD$ measures the centripetal force.

Joining $AB$ and $BE$, it is easy to see from similar triangles, that $AD : AB :: AB : AE$; hence $AD = \frac{AB^2}{AE}$.

But the chord $AB$ is ultimately equal to the arch, and therefore equal to the projectile velocity; hence, the centripetal force $= \frac{2}{2/3}$ vel.$^2$ centripetal force $= \frac{2}{2/3}$ deq. chord $^{\text{def. chord}}$

Prop. VIII.
If the body move uniformly in a circle, the centripetal force will be directly as the square of the projectile velocity, and inversely as the diameter.

For the centre of the circle will be the centre of attraction, (Prop. 6.), and hence the deflective chord will be the diameter. Hence, the Prop. follows from the last, $f = \frac{v^2}{r}$.  

Prop. IX.

If the body move uniformly in a circle, the centripetal force will be directly as the radius, and inversely as the square of the periodic time.

For in uniform motion, the velocity is proportional to the space divided by the time. Hence, let \( c \) denote the circumference, \( v \) the velocity, \( c = r \), but \( c \approx r \), therefore \( v \approx \frac{r}{t} \). Substituting this value of \( v \) in last Prop. we get \( f \approx \frac{r}{t} \).

Prop. X.

If the body move uniformly in a circle, the centripetal force will be directly as the product of the distance of the radius and the square of the angular velocity.

For let \( a \) denote the angular velocity. It is evident that \( t \approx \frac{1}{a} \) and \( t^2 \approx \frac{1}{a^2} \). Substituting this value of \( t^2 \) in last Prop. we get \( f \approx r a^2 \).

The four last propositions give us proportional equations, with regard to the revolution in a circle.

The two next afford us absolute equations, which are also of frequent use.

Prop. XI.

If the body revolve uniformly in a circle, the space through which it would move by the action of the centripetal force alone in any unit of time, such as a second, will be equal to the square of the radius described in the same unit, divided by the diameter, or twice the radius.

It appeared in Prop. 7, that the space through which the body would move in an instant by the action of the centripetal force, is equal to the square of the radius described in an instant, divided by the defunctive chord; which, in this case, is the diameter. But the space described in consequence of an attraction acting always with the same intensity, is proportional to the square of the time; and the motion in the circle being uniform, the arch described is proportional to the time; and, therefore, the square of the arch proportional to the square of time. Hence, the effect of the attractive force in any time is proportional to the square of the radius described in the same time; and, therefore, since the proposition holds in the case of an instant, it must hold in the case of any other unit; or \( f = \frac{v^2}{2r} \), the unit of time being the same for \( f \) and \( v \), but of any magnitude.

Con. 1. Of these three, viz. \( f, v, r \), any two being given, the third may be found.

Con. 2. The projectile velocity is equal to that which a body would acquire in falling through half the radius by the uniform action of the centripetal force.

For by the doctrine of accelerated motion, the velocity so acquired would be \( \sqrt{f \frac{v}{2}} = \sqrt{\frac{4r}{2}} \), and by the formula in this proposition, \( v = \sqrt{\frac{2r}{f}} \).

Con. 3. It is evident that this proposition, and the preceding corollaries, will apply to a circle described with a variable motion, if you substitute half the defunctive chord instead of radius, and the space that would be described in the same unit with an unaltered velocity, instead of the arch actually described.

Prop. XII.

If the body revolve uniformly in a circle, the space through which the body would move by the action of the centripetal force alone, in any unit of time, will be equal to twice the radius, multiplied by the square of the circumference of the circle whose diameter is unity, and divided by the square of the periodic time, or \( f = \frac{2 \cdot \pi \cdot m^2}{t^2} \), where \( m \) denotes the circumference of a circle whose diameter is unity, and therefore \( = 3.1416 \) nearly.

For the circumference of the given circle will be \( 2 \pi m \); and the motion being uniform, \( v = \frac{2 \cdot \pi \cdot m}{t} \), and \( v^2 = \frac{4 \pi^2 \cdot m^2}{t^2} \); but last Prop. \( f = \frac{v^2}{t} \); therefore \( f = \frac{2 \pi \cdot m^2}{t^2} = 19.739 \times \frac{r}{t} \) nearly.

Con. 1. Of these three, viz. \( f, r, t \), any two being given, the third may be found.

Con. 2. The periodic time is to the time of falling along half the radius by the uniform action of the centripetal force, as the circumference of a circle to the radius.

For, by the doctrine of accelerated motion, the time of falling along half the radius will be \( \sqrt{\frac{r}{2f}} \), and by the formula of this Prop. \( t = m \times \sqrt{\frac{2r}{f}} = m \times \sqrt{\frac{4 \pi^2 \cdot m^2}{t^2}} \). Hence the latter to the former as \( 2m : 1 \). This \( \frac{1}{2} \), that is, the circumference of a circle to radius.

Prop. XIII.

The centripetal force necessary to make a body describe a circle with the same angular velocity as it has in the different points of its orbit, of whatever form, is inversely as the cube of the distance from the centre of attraction.

For in circular motion \( f = \frac{r}{a^2} \) (Prop. 10.) and in any curve \( a = \frac{1}{r^2} \) (Prop. 4.) and \( a = \frac{1}{r^2} \), where \( r \) denotes the radius vector. Hence, \( f = \frac{r}{a} = \frac{1}{r^3} \).

Prop. XIV.

If one body describe a curve (BE) around a centre of attraction (c), and another descend toward that centre in a straight line (AC) by the mere action of the centripetal force, which is supposed to be the same at equal distances; and if in any two points (B, A) equidistant from the centre, the bodies have equal velocities, they will also have equal velocities in any other two points equidistant from it.

Take the indefinitely small arch BE. From C, as a centre, with the radii CB, CE, describe the arches BA, ED, the velocities at E and D shall be equal, for draw FG \( \perp \) BE.
The increments on the velocity, in describing these small spaces, will be as the product of the accelerating force by the time. Now, the velocities at A and B being equal, the times of describing AD and BE will be as the lines AD and BE. Again, the centripetal forces at A and B being equal, will be as the equal lines AD and BF; but the body at A is accelerated by the whole of the centripetal force; whereas at B, the centripetal force is to that which accelerates the body along the curve, as BF to BG; hence, the accelerations at A and B are as AD and BG. Hence, the increments on the velocities, in describing these small spaces, will be as AD$^2$ and BG$^2$; and therefore BG$^2$BE = AD$^2$. Therefore, the increments are equal, and consequently the velocities at D and E equal. Now, since, in making equal and infinitely small approaches toward the centre, the increments of velocity are equal, it follows that, in making equal finite approaches, the increments will be equal, and therefore the velocities acquired will be equal.

**Prop. XV.**

If the orbit which a body describes in consequence of a centripetal force, and which we may call the simple orbit, revolve from whatever cause in its own plane around the centre of attraction with an angular velocity, which bears a constant ratio to that of the body, the compound orbit which the body describes in consequence of this compound motion will be deflected toward the same centre of attraction.

For, in the compound orbit, the angular velocity of the body will be every where equal to what it had in the simple orbit, plus or minus the angular velocity of the orbit, according as the orbit revolves in the same direction as the body, or in a contrary one; hence (from the constant ratio mentioned in the enunciation) it is clear, that the angular velocity in the compound orbit will be every where proportional to the angular velocity in the simple orbit; but the angular velocity in the two orbits will evidently be proportional to the momentary increase of area, the distances being the same. Hence, the areas in the two orbits will increase at the same rate; but in the simple orbit, the areas are proportional to the times, (Prop. 1.) Hence this will also hold in the compound orbit, and hence this orbit may be considered as having the same centre of attraction, (Prop. 2.)

**Prop. XVI.**

The same supposition being made as in last proposition, the difference at any point between the centripetal force that acts on the body in the simple orbit, and that which acts on, or will be necessary to retain the body in the compound orbit, will be inversely, as the cube of the distance of the point from the centre of attraction.

To simplify the expression of the reasoning, suppose that the body is approaching nearer to the centre of attraction. It is evident, that the approach made in the same time will be the same in both orbits, since the mere revolution of an orbit cannot affect the distance of any point in it from the centre. The rate of approach being the same, but the angular velocity being different, it is evident, that the centripetal force must be different; less, for instance, where the angular velocity is greater. The approach made at any point in an instant in either orbit will be the excess of the centripetal force above what would be necessary to retain the body in a circle moving with the same angular velocity; hence the excess in the one orbit will be equal to the excess in the other. Let $a$, $b$ denote the centripetal forces in the compound and simple orbit; $c$, $d$ those in the circles described with the same angular velocities. It appears that $a-c = b-d$, hence transposing $a-c = b-d$; but in each orbit the centripetal force necessary to describe a circle with the same angular velocity is inversely as the cube of the distance from the centre (Prop. XVIII) and therefore the difference of centripetal forces necessary to do the same must also be inversely as the cube of the distance. Hence, at any point the difference of centripetal forces, employed in describing the orbits themselves, will be inversely, as the cube of the distance.

**Prop. XVII.**

If there be two free bodies, the one cannot remain at rest, while, by its attraction, it causes the other to move round it; but if the two bodies receive equal impulses in opposite parallel directions, their centre of gravity will remain at rest, and they will describe similar curves.

The first part of the proposition is manifest from the third law of motion, for as the one body attracts the other, the other will attract the first, and cause it to approach.

The second part will appear thus: Let $A$ and $B$ be the two bodies, $C$ their centre of gravity. It follows, (see Gravity,) that $AC$; $CB$; the mass of $B$; the mass of $A$, or shortly $B$; $A$. Let the bodies receive equal and parallel impulses in the directions $BF$ and $AG$, and suppose that (leaving out the attraction) the body $A$ would move along $AG$ in a moment; join $GC$, and produce it to $F$; $BF$ will be the line past over by $B$ in the same moment; for the impulses being equal, the velocities will be inversely as the masses, that is, directly as $AC$; $BC$, but by similar triangles $AG$; $BF$; $AC$: $BC$. Again, suppose that, in consequence of the mutual attraction, the bodies, in the moment alluded to, describe the curves $BD$, $AE$, then $GE$, $FD$ will be the momentary deflections.

The attractions being equal, $GE$ will be to $FD$: $B$; $A$, that is, $AC$; $CB$; $GC$; $CF$; and hence the remainder $EC$ will be to the remainder $CD$ also in the same proportion, viz. $B$; $A$. Hence the same point $C$ will still be the centre of gravity of the two bodies when they have arrived at $E$ and $D$, and hence it will be so continually.

Again, it is clear that the small arches $AE$ and $BD$ are similar, since all the straight lines connected with the one are proportional to the corresponding lines connected with the other. The arches described the next moment will be similar, for a like reason; and hence the whole arches described in equal finite times will be similar.

**Prop. XVIII.**

The same supposition being made as in last proposition, the curves described will be similar to the curve which one of the bodies would appear to describe to a spectator situated on the other, and conceiving himself at rest.

Suppose the spectator at $A$; Suppose that the Fig. 14. arches $AE$ and $BD$ are described in a moment, and may therefore be considered as straight lines. By the principles of apparent motion, the body $B$ will appear to move in the direction $BD$ with a vel. as the sum of the two velocities, viz. $BD$, $AE$. Hence, producing
DYNAMICS.

Application. BD to H, making DH = AE, BH will be the apparent motion of B. Join AH; it is parallel to CD, because HD is ≡, and || AE. Hence the Δ AHB is similar to the Δ CDB or ACE. In the same manner, the small Δ, apparently described, and that actually described the next moment, will be similar; therefore the curves apparently described, and those actually described in any finite time, will be similar.

Prop. XIX.

The same supposition being made as in the two last propositions, the times in which the bodies describe their curves, will be to the time in which one of the bodies would describe a similar curve around the other restrained from moving, as the square root of the mass of the other body to the square root of the sum of the masses.

Suppose that the similar arches described, BD, BH, are infinitely small; let BG be a tangent, then FD and GH will be the small deflections caused by the same force in the two curves. Now, when a force of pressure remains the same, the time is proportional to the square root of the space. Hence \( \sqrt{GH} : \sqrt{FD} : \sqrt{HD} : \sqrt{GH} : \sqrt{GD} : \sqrt{AB} \); that is, \( \sqrt{A} : \sqrt{A+B} \).

Hence time in BD : time in BH :: \( \sqrt{A} : \sqrt{A+B} \).

The same ratio will hold with regard to the next two applications.

Cor. The bodies will describe areas proportional to the times around the centre of gravity. For by the proposition, the times of describing similar sectors are in a constant ratio; and it is easy to see that similar sectors are in a constant ratio. But in the large figure, the sectors described are proportional to the times, (Prop. 1.) therefore this must hold also in the small figures.

Supposing the body to have bulk, it can be shown that a force passing through its centre of inertia or of gravity will produce the same effect as if the whole mass were collected in that point, and that in any other direction it will produce two motions, the one rotatory, and the other progressive: See Rotation. The discussion of Central Forces, given above, exhibits some of the chief cases of the action of bodies on one another at a distance. The article Astronomy Physical exhibits others. The action of bodies on one another in contact will be given under Impulse; and their action on one another through the medium of a third, will be seen under Mechanics.

On Dynamics, the reader may consult La Grange's Mechanique Analytique; D'Alembert's Dynamique; Gregory's Mechanics. (T. B.)

DY N

DYNAMOMETER, from dynamus strength, and μέτρησις a measure, is the name of an instrument for measuring the relative strength of men and animals.

The dynamometer invented by Mr George Grahame, and improved by Dr Desaguliers, consists of a strong frame of wood, ABCD. Through the piece DC is a hole D, sufficiently large to admit a cylindrical iron rod, about an inch in diameter. Upon this bar is a square to receive the two separate and unequal arms of a bent lever DE, DE, which are kept tight in their place by a strong screw nut d. The arm DE, which carries a weight W, is prevented from falling below a horizontal position, by a metallic pin at K, which stops the arm DF in its progress towards C, but both the arms move freely in the opposite direction. At the top of the arm DF, seen separately at df, is a round cross bar about six inches long. The iron piece LN, also seen separately, has likewise a cross bar at top, and holes for iron pins to fasten it in its place. Another piece of iron HGI, seen separately at hgi, is fastened to the timber that carries the lever by a strong wooden screw at I, and by the pin k going through its wings and the timber. The collar S is to be put on when the upright arm of the lever is not used, and M is the centre of gravity of the steel-yard DE.

In using this machine, the person who wishes to try his strength, must take hold with his left hand of the round part of the cross at N, and of the round part of the cross at F with his right hand, and then by bringing his right hand towards the left, in the direction FN, he will move DE, and elevate the weight W. When this weight is lifted up so as to make the arm ED just quit the pin at K, the force of the arm will be determined in the following manner: Suppose the weight W to be 56 pounds, and the distance from the fulcrum, viz. WD, fifteen inches, then the momentum of W will be \( 56 \times 15 = 840 \). Let us suppose also, that it requires six pounds applied at M, the centre of gravity of the steel-yard, to balance the steel-yard itself. Then if MD = 10, we shall have \( 6 \times 10 = 60 \) for the additional resistance made to the force of the arm; so that the whole resistance will be \( 840 + 60 = 900 \), which divided by \( FD = 10 \) inches, the distance of the power, will give ninety pounds for the force of the man's arms when applied at F and N. If another man is capable of raising double the weight W, added to double the weight of the steel-yard at M, he will be twice as strong. Instead of increasing the weight at W, the weight may be removed towards E. Desaguliers has described several variations in the construction of this machine, and has given a drawing and description of an instrument for measuring the strength of the fingers; but for an account of these, we must refer the reader to his Course of Experimental Philosophy, vol. i. p. 291, 292. Annot. on Sect. iv.

The dynamometer invented by Leroy of the Academy of Sciences, consisted of a metal tube, ten or twelve inches long, placed vertically on a stand, and containing a spiral spring, having above it a graduated shank terminating in a globe. This shank, together with the spring, was pressed into the tube in proportion to the force which was applied to it, and pointed out upon the graduated shank the strength of the person who exerted the force.

Regnier's dynamometer, however, is that which was invented by Regnier, and of which we have given a representation in Plate CXXLI. This instrument, which resembles a common graphometer in its form and size, consists of a spring AA twelve inches long, and bent into the form of an ellip.
The places are Myriogrammes.

Fig. 2.

A piece of steel B, Fig. 3, is firmly fastened to the spring by means of a claw and screws, and is intended to support a semicircular plate of brass C, Fig. 2, for receiving the scales or graduated arcs. The outermost of these arcs is divided into myriogrammes, and the other into kilogrammes. Each of these arcs is still further subdivided by points, which express the weight in pounds marce; and the various parts of the scale are determined experimentally, by appending accurate weights to one of the extremities of the elliptical spring. On the other branch of the spring, is a small steel support D, furnished with a horizontal cleft at its upper extremity, to receive freely a small copper lever E, which is kept in its place by a steel pin a. This part of the machine is represented on an enlarged scale in Fig. 4.

In the centre of the semicircular plate C, (Fig. 2), a light steel index F is fixed upon its axis by a screw, and has a double point, viz. at m and n, for indicating the divisions on both scales. A small piece of leather, or cloth, is glued upon the lower side of the circular part C, to render uniform, and diminish the friction on the plate. The point m of the index, and the scale of myriogrammes is employed in all experiments, in which the spring is to be pulled in the direction of its greater axis AA, and the point n and the scale of kilogrammes is used, when it is to be employed for experiments in which the two sides of the spring are to be compressed.

The mechanism now described is covered with a small plate of brass CD, Fig. 5, to prevent it from being injured. Upon this plate is a divided arc, corresponding with the first arc of the machine, and by the play of a small index b (Fig. 4) under the plate, the movements of the spring may be ascertained. Through the aperture K, a small turn screw is introduced, for the purpose of relieving or tightening the index, when necessary.

A pallet of brass L, Fig. 3, has a screw, with a cap like that on the needle in the mariner's compass, in which the lower pivot of the lever that pushes round the index is made to play. This pallet, acting like a spring, yields to any sudden concussion, and prevents the mechanism from being deranged. M (Fig. 5) is a socket rivetted on the plate CD, in which the upper pivot of the lever turns. N, N, N, are small cylindrical pillars, to which the plate CD is fixed by three screws.

When it is intended to try the strength of the human body, it is necessary to have an iron rack, Fig. 6, on the lower part of which the feet of the person must rest; and also a double handle of wood, with an iron hook, Fig. 7, which he must at the same time hold with both his hands.

When the strength of animals is to be determined, it is necessary to have a double iron hook, shewn in Fig. 8, one end of which is to be hooked to the end of the spring, and the other to a rope fixed to a stake, as at c, c, Fig. 9.

The three methods of using the dynamometer, are represented in Fig. 9, 10, and 11.

Fig. 9, represents the method of applying the dynamometer, to ascertain the strength of animals. The animal is yoked to the chains PQ, and the force which it exerts against the fixed obstacle R is shown by the index of the interposed dynamometer T. The pin d, Fig. 4, pushes forward the index, which always remains at the place to which it is brought. M. Regnier made experiments with four excellent horses, and obtained the following results:

<table>
<thead>
<tr>
<th>Myriogrammes.</th>
<th>Force exerted by the first</th>
<th>second</th>
<th>third</th>
<th>fourth</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>36</td>
<td>38½</td>
<td>30½</td>
<td>43</td>
</tr>
</tbody>
</table>

which is equal to 730 pounds marte.

Fig. 10 shows the method of determining the strength of the hands, or the muscular force of the arms. The person lays hold of the two sides of the spring nearest to the centre, so that his arms may be a little stretched and inclined downwards, at an angle almost of 45 degrees. This position is considered by Regnier as the most natural, and as that in which a man can exert his whole force. The index will then point out on the scale of kilogrammes the force which has been exerted. The strength of each hand may be tried separately, and the sum of the two will always be found equal to that of both when exerted together.

Fig. 11, represents the method of measuring the strength of the reins of the human body. The person places his feet on the bottom part of the rack, shewn separately in Fig. 6, after one of the ends of the spring has been placed in one of the hooks of the rack, and the hook of the handle, Fig. 7, put in the other end of the spring. The strength which he exerts in this position is then indicated upon the scale of myriogrammes.

The preceding dynamometer is obviously an instrument of great use; and as it does not weigh more than two pounds and a half, there are few practical purposes to which it may not be conveniently applied. For cases, however, where the load or the resistance is stationary, as in those represented in Fig. 9, 10, and 11, we think that a much simpler and more accurate dynamometer might be constructed in the following manner.

Let ABCD be a vessel containing water, and EF a long cylinder, made of any substance heavier than water, suspended in the fluid by a rope GHI attached to the hook G, and passing over a pulley H. When the upper surface E of the cylinder is on a level with the surface of the water, the weight of the cylinder, or the force which it exerts upon the rope GHI, will be equal to the absolute weight of the cylinder in air, diminished by the weight of a quantity of water of the same magnitude as the cylinder. When a horse or a man pulls at the rope HI, so as to raise the cylinder above the fluid surface, the weight of the cylinder will gradually increase; and if the magnitude and specific gravity of the cylinder are duly adjusted to the description of force which is applied, there will be a particular position of the cylinder, at which its weight will exactly balance the force which is applied at I. The forces which are then in equilibrio, or the force required to be measured, will be equal to the absolute weight of the cylinder diminished by the weight of a quantity of water equal to the magnitude of the immersed part of the cylinder. In this way the force of men and animals, and of particular parts of the human body, may be ascertained with the utmost accuracy and facility; and by fixing a scale upon the cylinder, the measure of the force in cwts. or pounds may be seen by simple inspection. The length of the
DYSART, the name of a royal burgh of Scotland, situated on the north side of the Firth of Forth. About the beginning of the 16th century, when Dysart received its charter, it was one of the most opulent and flourishing towns in Fife; but since that period its trade has undergone several fluctuations.

The harbour, though very much exposed, is susceptible of great improvements. The trade of the town was formerly carried on by means of twenty-four square rigged vessels; but the town has now only eight vessels of the description, and a sloop.

The principal exports of Dysart are salt, coals, ironstone. About 17,100 bushels of salt are annually exported. Nearly 15,000 tons of coal are raised every year, and about 3200 tons of ironstone are exported annually to the Carron works. This ironstone yields commonly 12 cwt. of metal per ton of ore. About 500 looms are employed in the manufacture of checks, of which about 530,000 yards are made annually. A number of hanks were formerly employed in building ships, but this branch of business has recently been laid aside; though, from the promising aspect of public affairs, this and the other manufactures of the burgh are beginning to revive. A greater degree of activity already appears in the harbour, and it is hoped that the revival of the Baltic trade will restore to Dysart its former commercial importance.

At a very short distance from the town is a mineral well, which is supposed to be of the same quality as the Pitcaithley water. It is covered by the sea at high water during spring tides. Population of the town about 1730, and of the parish 5385. See Fifeshire.

E.

La Perouse, however, saw one which was 300 feet long, 10 broad, and 10 high, and capable of holding 200 persons.

Easter Island abounds with monuments and statues, which appear to bear the character of antiquity. The monuments are small pyramidal heaps of stones, the upper stone being whitened with lime water, and are erected near the sea shore. The statues, which are of a gigantic size, are raised on platforms of solid masonry, 35 feet long, 14 feet broad, and from 3 to 12 feet high. They are faced with hewn stones, and are specimens of excellent workmanship. Although no cement is employed, yet the joints are very close, and the stones are morticed into another with great skill. The statues are rudely sculptured out of a volcanic production. The nose and chin are not badly shaped; the ears are out of all proportion, and the bodies have no resemblance to the human form. The largest of these statues is about 14 feet six inches long, seven feet six inches across the shoulders, three feet thick and six feet broad in the belly, and five feet thick at the base.

Only three or four canoes were seen. They were about 19 feet long, and seemed unfit for any distant navigation.

According to Captain Cook, the population did not exceed 400 or 700, about one-third of whom were females. In 1765, La Perouse considered the population as nearly 2000, and saw no marks of their being upon the decline. See Cook's Second Voyage, vol. 1. and La Perouse's Voyage, vol. 2.

EASTER, is the name of a feast of the church held in memory of the resurrection of our Saviour. See Chronology, p. 411.

EASTER ISLAND, is the name of an island in the South Pacific Ocean, situated in West Long. 190° 46' 20", and South Lat. 27° 5' 50". It is supposed, without much reason, to have been visited by Captain Davis, in 1686. It was touched at by Roggewein in 1722, and has since been visited and examined by Captain Cook in 1774, and La Perouse in 1785.

This island is from 30 to 35 miles in circumference; its surface is mountainous and stony, and the hills rise to such a height, that they are visible at the distance of about 8 miles. On the north-east coast of the island, the land is remarkably high; on the south-east, the shore forms an open bay, where Roggewein is supposed to have anchored. On the south are two rocky islands, and, about three miles to the north of the south point, is Cook's Bay, having 80 fathoms of water over a sandy bottom, at the distance of three quarters of a mile from the shore. This bay, however, is very dangerous when westerly winds prevail.

At the southern extremity of the island is the crater of a volcano, of great size, depth, and regularity. It was like the frustum of a cone, whose upper and lower bases appeared more than two miles in circumference, and it was at least 800 feet deep. The marsh at the bottom was surrounded with plantations of bananas and mulberry trees, and contained several pools of fresh water, apparently on a level with the sea.

Although the soil is so exceedingly fertile that three days' labour is sufficient to procure the Indian subsistence for a year, yet only about a tenth part of the island is under cultivation; the rest being covered with a coarse kind of grass, which extends to the tops of the mountains. The cultivated portions are of an oblong form, without any enclosures. The weeds are carefully pulled up, and burned in heaps to fertilize the soil; and the soil is kept cool and moist by large stones that lie loose upon the surface. The principal productions of the island are potatoes, yams, tararoreddy root, gourds, plantain and sugar-canes.

The appearance, dress, language, and manners of the people, has such an affinity to those of the other South Sea islanders, that it would be unnecessary to give any particular account of them in this article. The females offered their favours for presents, and the men assisted in this interchange of commodities. They even dragged along girls of 13 or 14 years of age, with the hope of receiving a part of the reward. Their houses are formed of upright sticks, bent towards each other, and tied at the top; and one of them, seen by Captain Cook, was 60 feet long, nine feet high in the middle, and three or four at each end, its breadth being nearly equal to its height.
being six cubits in length and three in breadth. Daniel
is said by Josephus to have built one of its most mag-
nificent palaces, some of the beams of which were of
silver, and the rest of cedar plated with gold. This
splendid edifice afterwards served as a mausoleum to
the kings of Media; and is affirmed by the last men-
tioned author to have been entire in his time. There
are no traces now remaining of these lofty buildings;
and even the site of this celebrated city has become a
subject of dispute among modern travellers. Sir John
Chardin fixes upon Tanis as the most probable situa-
tion; but, at the same time, admits that no remarkable
ruins are to be seen there; and that the materials of
those, which have been found, are different from those
which the Medes employed in the structure of their
palaces. Others suppose it to be Hamadan; and some
Gasien in the province of Yerrak. Merodach, whom
some suppose to have been Nebuchadnezzar, overthrew
Dejoces, and defied his capital, A. M. 3347; and it
was more fatally pillaged by the army of Alexander,
A. M. 3725. See Ancient Univ. Hist. vol v. p. 4;

ECCLESIASTICAL HISTORY.

There are two aspects in which the church of Christ
presents itself to the notice of impartial history. It
may either be regarded in its connection with the civil
and political establishments existing in the world, or it
may be viewed as a separate and distinct society, reared
upon its own principles, and possessing a character and
features exclusively belonging to it. Ecclesiastical his-
tory therefore respects, either the support which Chris-
tianity has received from the secular power, together
with the benefits or the disadvantages resulting from this
support; or as it respects the internal administration of
the church, its constitution and discipline, its doctrine
and its worship. Under the first of these heads, we
shall be able to trace the rise and the decline of priestly
usurpation, and especially that of the papacy; and un-
der the second, we shall have it in our power to mark
the revolutions of theological opinion, connected as they
have uniformly been with those of philosophy and litera-
ture, during the long period of eighteen centuries.
Under the one or the other of the divisions now men-
tioned, almost every thing interesting or profitable in
ecclesiastical history may be conveniently introduced.
In the following article, therefore, we shall endeavour
to keep these divisions steadily in view.

The period of eighteen centuries, above alluded to,
may be separated into four great portions. The first
extends from the birth of Christ to the reign of Con-
stantine A. D. 325, when Christianity became the re-
ligion of the empire. The second reaches onward
from the time of Constantine to the year 755, when the
supremacy of the Pope was acknowledged, and his tem-
poral domains established. The third portion extends
from the acknowledgment of the Pope's supremacy and
the establishment of his temporal dominion, to the era
of the Reformation, about the year 1580. And the last
portion includes the interval between the era of the re-
formation and the present time.

CHAP. I.

The History of the Church from the Birth of Christ to
the reign of Constantine, A. D. 325, when Christianity
became the Religion of the Empire.

In the 753d year of Rome, and in the reign of Au-
gustus Caesar, Jesus Christ was born. The place of
his nativity was Bethlehem in Judæa, and his reputed
father was Joseph, a carpenter of Galilee. At the time
of his birth, the whole world was at peace. The events
of our Saviour's life, which are recorded in the four
evangelical histories that have come down to us, are
well known to his followers, and it is upon the efficacy
of his vicarious sufferings and propitiatory death, that
all true Christians build their hopes of everlasting hap-
piness. Sometime previous to his ascension into heaven,
the founder of our religion gave a charge to his apostles,
commanding them to preach the doctrine which he had
taught them, and assuring them that they should be
furnished with extraordinary gifts as the evidences of
their commission. The words of the charge, which has
been preserved by the evangelist Matthew, are these,
"Go ye, and teach all nations, baptizing them in the
name of the Father, and of the Son, and of the Holy
Ghost." And another of the inspired writers informs
us, that they were instructed to wait at Jerusalem, till
they should "receive power by miraculous communi-
cation from heaven. In obedience to their Master's in-
junction, we find the apostles remaining in the Jewish
capital, and "when the day of Pentecost was fully
come" they were all assembled in one place. "And
suddenly there came a sound from heaven as of a shis-
ing mighty wind, and it filled all the house where
they were sitting; and there appeared unto them clo-
tened tongues, like as of fire, and it sat upon each of them.
And they were all filled with the Holy Ghost, and did
speak in tongues as the Spirit gave them utterance." In
this way the promise of Jesus was accomplished.
The Holy Ghost was poured forth in mighty strength
upon the apostles. They were furnished with extra-
ordinary powers, and especially with the gift of tongues.
And Saul of Tarsus having seen Jesus after his ascen-
sion, "as one born out of due time," and having been
miraculously called to the apostleship, those first mis-
sionaries of the faith, proceeded in the great work of
turning mankind from darkness to light, from ignorance
and wickedness, to knowledge, to righteousness, and to
peace.

The reception of the new doctrine varied according to
the circumstances in which the apostles were placed.
In general, however, it met with a very great degree
of opposition, and the preachers were frequently re-
duced to the necessity of exercising their functions at
the hazard of their lives.

The Jews, having persecuted our Saviour from the sects among
commencement of his ministry, and having at length the Jews
succeeded in putting him to death, could not be ex-
pected to treat his disciples with greater lenity. At
this time, there were three sects, or descriptions of men,
considered in a religious and political point of view,
among the Hebrew people; and each of these sects
seemed to vie with the others, in marked and zealous
opposition to the Christian cause. However much they
Ecclesiastical History.

differed from one another in the principles which they
professed; they agreed in rejecting the claims of Jesus;
they considered him as a pretender to the character of
the Messiah; and thought it not only innocent, but mor-
ritorious, as well as necessary, to suppress the religion
which he taught.

The sects alluded to were the Pharisees, the Saddu-
cees, and the Essenes. The Pharisees were the Thera-
peutae of Judea; a class of men who lived, or affected
to live, in contemplative retirement, and to take no
part in the concerns of the state. They are not men-
tioned in the sacred books; but from other sources of
information we learn, that they held the doctrine of the
malignity of matter, ascribing all evil passions to the
body, and attempting, by abstinence, silence, and other
varieties of mortification, to purify the soul, and to
prepare it for heaven. While they acknowledged the law
of Moses, they regarded the Pentateuch as a collection
of allegorical and mysterious truths; and of course the
chief labour and difficulty of their theology, was to find
the hidden meaning, the holy and celestial import which
the literal enunciation was supposed to conceal. Of all
the Jewish sects, the Pharisees appear to have made, in
point of fact, the least opposition to the progress of
Christianity. The Sadducees were the unbelievers in
religion. They denied the existence of angels or spir-
its, contending, that man stood at the head of all the
works which God had made; and they rejected the no-
tion of the soul's immortality. Their scepticism, how-
ever, had its limits; for they admitted the books of
Moses, and received them as the communications of
heaven to the great legislator of their nation; but they
refused the other parts of the sacred canon, except in
so far as they contained the civil and political history
of the Hebrew people. Though not remarkable for
their numbers, they were of great consideration in the
state. Their influence in the Sanhedrin was such as
to render it necessary to court their favour. Many of
the sect were rich, many of them learned; and they
enjoyed, almost exclusively, the patronage and pro-
tection of the great. During the course of our Savi-
our's ministry, they proposed to him many insidious
questions, either with a view to confound him by their
skill in argument, or to expose him to the resentment
of the Roman procurator, or to the derision of the
people. And when the apostles of Jesus discoursed to
their hearers of a resurrection and a future judgment,
doctrines so completely opposite to the tenets of the
Sadducees, this powerful sect soon proved themselves
to be the most violent of all the persecutors and op-
pressors of Christianity.

In point of numbers, however, as well as influence over
the public opinion, the Sadducees were constrained to
yield to the Pharisees. This last was by far the most po-
pular of the Jewish sects. Their errors, if not more deep-
ly rooted, were more extensively diffused; they presided
in the schools; they were the chief doctors of the law,
the favourite expositors of the Levitical institute, and in-
terpreters of the prophecies; and, in the estimation of
the multitude, they were the surest guides to a holy life.
If the creed of the Sadducees was wrong, the Pharisees
were ample believers. They received the books of Mo-

was in the power of the Pharisees to alter or to modify
them at pleasure. Hence it was that the precepts in
question were so managed in the application, as to in-
crease the wealth, and support the pretensions, of this
predominating sect. Hence it was that the Pharisees
"devoured widows houses" with impudence, and "bound
heavy burdens upon the poor," which they themselves
would not touch with one of their fingers. And hence
it was that our Saviour, after pronouncing a woe upon
them, declares, that they "had made void the law, that
their traditions," and the precepts connected with it,
or illustrative of its enactments, by their traditions.
The character of the leading persons belonging to this
sect was such, as to excite the highest aversion and
disgust of every enlightened and well-regulated mind.
They were very far from having attained to that pure
and heavenly virtue which the people ascribed to them.
Though most scrupulous and elaborate in the exercises
of piety, they were not devout; with long prayers in
their mouths, they fancied themselves in need of no
spiritual gift; and while they enlarged their phylac-
teries, and paid tithe of mint, and anise, and cum-
in, they neglected the great and necessary duties of
justice, mercy, and truth. They afforded us the most
complete specimens of meditated and consummate hy-
pocrisy, and constitute the most perfect examples which
the New Testament exhibits, of all that we are bound
to avoid and to abhor.

The hatred of the Pharisees towards Christ and his
apostles, was marked by its extraordinary virulence.
From some incorrect interpretations of the prophecies
they had figured to themselves the Messiah as a mighty
deliverer, who was to rescue the Israelitish nation
from the oppression of the Roman yoke, and subject the whole
world to the institutions and the authority of Moses.
Our Saviour was not the deliverer whom they expected;
he appeared without the pomp and splendour of royal-
ity; without armies or attendants; and he declared, in
the plainest manner, that his kingdom was not of this
world. The pride of the nation was offended, and the
opposition of the Pharisees was roused in all its bitter-
ness and malignity. After repeated and fruitless at-
tempts to involve Jesus in some charge which might
affect his life, they succeeded in gaining over one of
his immediate followers, and by the well-known trenched
of Judas Iscariot, he was given up to their fury.
It was the impetuous zeal of the Pharisees that urged
the Roman procurator to put our Saviour to death. It
was the Pharisees who sealed the stone which covered
the mouth of the sepulchre; and it was the same ac-
tive and persevering party that bribed the soldiers who
watched the grave, and instructed them to publish the
false account of the resurrection. They were the chief
agents in the martyrdom of Stephen. They granted to Saul the commission which authorized him to bring
the Christians of every description bound to Jerusalem.
And by their ill-supported expositions of the sacred
books, and the delusive hopes with which they flatter-
ed and amused the people, they urged on the destiny,
and precipitated the destruction of their country. Grain-
ing under the severities of a foreign administration, ser-
verities reviled by the face of the Roman governor and
an impatient spirit of the Jews, this unhappy people
at length broke out into open rebellion; and still
dreaming that the era of deliverance was at hand, they
rashly and foolishly set the Roman power at defiance.
The war raged throughout Asia Minor and a great part
of the East. The armies of the empire, under the or-
ders of Titus, marched into the sacred territory. The
chief city of the Jews was besieged, and for six long
months its devoted inhabitants were subjected to all that extremity of suffering with which offended heaven is wont to chastise the aggravated disobedience of man. The Romans assailed them from without, while famine and discord, with the delusions of hope, and the determination of despair, destroyed them within the walls. At length, in the 70th year of the Christian era, Jerusalem was taken by storm, and its temple reduced to ashes. And the prophecy of Jesus was literally accomplished, that of this lofty and splendid edifice, the pride of Palestine, not one stone should be left upon another which should not be thrown down. Eleven thousand of the Jews perished in the siege and in the assault; an incredible multitude of them were carried away to be sold as slaves; and the markets became at last so glutted, that no purchasers were to be found. The altar of God was thrown from its place, and broken in pieces; the sacrifice and the oblation ceased, and the smoking ruins proclaimed "that the glory was departed." Amidst these calamities, the followers of Jesus, who had increased to a considerable number under the ministry of Peter and John, availed themselves of a favourable opportunity; and in compliance with our Saviour's instructions, withdrew from the city and the horrors of the siege. They retired to Pella, a small town beyond the river Jordan, and continued for a while united among themselves, and undisturbed in the exercise of their religion.

Among the Gentiles, the progress of Christianity was distinguished at once by its extraordinary rapidity, and the apparent inadequacy of the means employed to publish it. In an article of this kind, it is impossible to shew at any great length in what respects the different systems of philosophy which prevailed in the ancient world, were at variance with the doctrines and precepts of our religion. But there is one observation which we feel ourselves constrained to make, and it is this: that whatever might be the philosophical systems of antiquity, and however wide the distinctions which separated them from one another, the patrons of all those systems, the masters of all the schools, agreed in supporting, with the whole weight of their authority, and the whole effect of their example, the religion acknowledged by the state. Whether with the Epicureans, a refined atheism was maintained, and pleasure was courted for its own sake, or whether with the Stoics it was believed that happiness consisted in a repulsive and untractable virtue; whether truth was supposed to be attainable by human endeavours, or all was pronounced to be uncertain, fluctuating, and momentary,—it was universally held to be the part of a wise and patriotic man, to comply with the religion established in the country to which we belong. Even Socrates, who seems to have expressed himself more openly than others with regard to the Paganism of his time, is known to have sacrificed a cock to Asclepius, a very short time previous to his death. Indeed it appears to have been an opinion by no means uncommon among the different sects of philosophers, that all the forms of religion were equally useful in governing the people, and equally destitute of a foundation in truth. To interfere with the acknowledged religion, therefore, was regarded not only as unnecessary, but as imprudent and pernicious; and he who should attempt to overturn it altogether, and to substitute another religion in its place, was represented as an innovator, whom it was incumbent on the magistrate to resist and to punish. The opinion, as we have mentioned, was general; and the practical consequence was, that the philosophers of Greece and Rome were sometimes found among the keenest opposers of Christianity, and the most cruel persecutors of its ministers. Besides, there was nothing in the religion of Jesus which was calculated to fill the imagination of the statesman, to excite his ambition, or to reward his activity. It was not associated in the mind with ideas of political glory, or recommended by any connections, real or imaginary, with military success. The founder of the new system belonged to a hated nation, and he had suffered a public and a disgraceful death: the apostles and evangelists were poor men; they could make no promises of wealth or distinction; they had no rewards to allure the covetous, and no honours to bestow on the vain. "Silver and gold have I none," says St Peter to the cripple whom he was about to cure, "but such as I have I give to thee.—In the name of Jesus Christ of Nazareth, rise up and walk."

The case was very different with the popular superstition. The prosperity of the state was intimately associated with its religious institutions, and the glory of its military commanders with that of the gods under whose auspices they had fought. Among the Romans, in particular, the same individual was at once the progenitor of the nation, and an object of their religious worship. The standard under which this victorious people had subdued the world was the bird sacrificed to Jupiter; the capitol, the great object of their reverence, and the sight of which never failed to awaken and to elevate their patriotism, was consecrated to the same divinity; the national history was filled with instances of oracular warning, or of protecting care; and, in one word, all that could engage the attention, and rivet the attachment, of the politician or the citizen, was identified with the existence and the honour of the gods. Nor was this the whole matter. The Pagan superstition had its intrinsic and peculiar attractions. Many of its observances were such as recommended themselves, in the strongest manner, to the most powerful tendencies and passions of our nature. In the worship of Venus, prostitution was an acknowledged part; the festivals of Bacchus were scenes of intoxication and riot; and the very father of gods and men himself, to whom there was none equal or second in authority or in place, was, in many particulars of his history, a notable example of cruelty and debauchery. Religion is the imitation of the gods which are worshipped. The people were not reluctant or slow to comply. A system which allowed of such indulgencies, and afforded such examples, was not likely to be speedily abandoned. It had enlisted the ruling passions on its side; it had fixed its dominion in the heart, and there seemed to be no power on earth which was equal to the task of driving it from its place. It was the ancient religion, it was sanctioned by the learned and the wise, it was patronised by the rich and supported by the great, it was closely associated in the minds of men with the national glory, and it had captivated and enslaved the people by its splendid rites and licentious indulgences. What, then, must have been the opposition which Christianity was doomed to encounter! And how great must have been the labours and the patience of those who were commissioned to preach its doctrine, and to establish it in the world!

The labours and the patience of the apostles were, Miraculous undoubtedly very great; but it is not to these alone gifts, that we must ascribe the rapid progress of Christianity. While we give all credit to the early teachers of our religion for their unextinguishable zeal and unwearied activity, we must not forget that their apparent means
